OPERATION FOR STRANGULATED HERNIA WITH GANGRENE.—Mr. H. W. CARSON operated on a feeble old man, æt. 84, who had been suffering for seven days from strangulation of a femoral hernia. When admitted to the hospital, the patient was in an extremely weak condition; the pulse was rapid and irregular; he had been vomiting on and off for a whole week, and during the last twenty-four hours his vomit had become feculent. The abdomen was not distended, nor were there any complications such as bronchitis, which might have been expected in a man of his age. It was decided to operate at once, and in view of his condition it was thought advisable to operate under a local anæsthetic. One drachm of a mixture of equal parts of adrenalin chloride and a 4 per cent. solution of eucaine was injected under the skin covering the hernia, and the operation was commenced after a lapse of ten minutes. The sac was extremely thin, and contained a piece of omentum and a small loop of small intestine, which was in a condition of partial gangrene. The constriction at the neck of the sac was divided, Gimbernat's ligament notched, and the intestine drawn down into the wound. The intestine was found to be more seriously damaged at the constricted part than elsewhere, the gangrene having resulted in perforation at that point. The gangrenous loop was incised, tubes fixed into the proximal and distal ends, and the loop of gut attached to the edges of the skin incision. A free discharge of fæcal matter followed from the proximal end, and arrangements were made for this to be carried away through a long tube attached to the tube in the proximal end. Mr. Carson said that the treatment of a strangulation in which the gut is not viable must necessarily depend altogether on the condition of the patient. In a case such as the one he had just operated upon, it was obvious that the most that could be hoped for was to relieve the obstruction for the moment, and this could be best and most rapidly done by adopting the practice of immediate drainage. If, on the other hand, one were dealing, he pointed out, with a patient who was in a condition to stand a somewhat prolonged operation, many surgeons advocated the immediate performance of intestinal anastomosis following upon resection of the affected gut. This can be done through an incision in the middle line of the abdomen or by carrying the original incision upwards and dividing Poupart's ligament. In either case there was a definite risk of infecting the peritoneum. If the patient's condition did not allow of immediate performance of such an operation as this, an artificial anus should be formed by opening the loop of intestine *in situ*, and an operation for the restoration of the continuity of the intestinal canal could be undertaken at a later period. The time at which this must be done depends, he said, not only on the recovery of the patient from his condition of shock and toxæmia, but also on the part of the intestinal canal implicated by the hernia; that is to say, were the portion of gut implicated high up in the intestinal tract it would be necessary to operate earlier than were it lower down; in other words the nearer the implicated bowel is to the lower end of the small intestine the longer is the period which can be allowed before the second operation; the reason for this, Mr. Carson said, was that the patient loses strength very rapidly if the upper part of the intestinal tract is drained by a fæcal fistula owing to lack of nutrition. A ready means of determining the part of the bowel involved lay in the fact that the intestinal wall becomes gradually less bulky from above downwards, while the mesentery, which is thin and semi-transparent in the upper part of the jejunum, becomes thick, opaque and laden with fat towards the lower end of the ileum. With reference to the subsequent operation, Mr. Carson said that there were two methods by which this could be done: the first consisted in opening the abdomen, withdrawing the herniated loop (frequently a matter of some difficulty), excising it, and restoring the continuity of the intestinal canal by an end-to-end or lateral anastomosis. The mortality of this procedure was considerable, and Mr. Carson recommended that a more extensive trial should be given to an alternative method, which consisted in performing a lateral anastomosis between the proximal and distal limbs of the herniated loop within the abdomen, the herniated portion being left with its artificial anus untouched. The success of this latter operation, he considered, depended upon the formation of a large communication (not less than two inches) at the point of the lateral anastomosis; the herniated loop was thus excluded; fæces soon cease to pass through the artificial anus, which will gradually close. The advantages of this operation, he thought, were: freedom from the risk of contaminating the peritoneum, rapidity of procedure, and avoidance of shock.

TRANSACTIONS OF SOCIETIES.

[BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD NOVEMBER 8TH, 1906.

The President, Mr. F. BOWREMAN JESSETT, in the Chair.

SPECIMENS.

MR. J. FURNEAUX JORDAN exhibited the following :—

1. FIBROID OF THE OVARY.

Mrs. S., æt. 59, was sent to me by Dr. Anderson, of the Birmingham General Dispensary, at the end of September last. Two and a half years previously he had diagnosed a definite tumour in the abdomen, had advised operation, but had lost sight of her. He did not see her again until September of this year, when he sent her to me. She was a big woman, and for a long time had been a drinker. Her children were sixteen in number, and it was nine years since she last menstruated. For three years she had been getting larger in the abdomen, and on admission measured 51 ins. round at the umbilicus. The enormous enlargement of the abdomen had for some months caused her distress in breathing, and for over four weeks before admission she had been confined to her bed. Her sufferings were increased by a hypostatic congestion of the lungs and by a large umbilical hernia. She was in constant dread of the latter bursting. The swelling of the abdomen was obviously due to ascitic fluid combined with a tumour which I thought to be ovarian. Her pulse was quick and feeble. I kept her in bed at the Women's Hospital for a few days, propped her up, and gave her strychnine and digitalis. On October 18th I operated. The abdomen was emptied of the ascitic fluid and the specimen you see there removed. I also repaired the umbilical hernia. The specimen proved on section to be a solid fibroid tumour of the right ovary, very hard, with no signs of degeneration anywhere. On the outside, distinct in parts, was a capsule formed of ovarian tissue. A microscopic slide, kindly prepared in the pathological department of the Birmingham University, is on the table showing the fibrous nature of the tumour and the ovarian tissue covering it. The patient has made an excellent recovery.

2. SOFT MYOMA OF THE UTERUS.

Mrs. W., æt. 48, was also sent to me in August last by a General Dispensary doctor, Dr. Moorhead. She had been married twenty-nine years, and had twelve children, the youngest æt. 10. Fifteen months ago her periods began to appear too often—every two or three weeks—and the quantity lost rapidly amounted to a flooding. For six months before admission to the hospital she had been in bed, but in spite of this the floodings were frequent and getting more and more prolonged. For nine months she had felt a "lump" in the abdomen and noticed it getting steadily larger. On admission on October 11th last, she presented all the appearances of one who has had severe hæmorrhages. She could not sit up in bed without feeling faint, her pulse was quick and feeble. On the other hand, she could take her food well and for a week before the operation was taking large quantities of milk. In the abdomen there could be felt a large nodular, distinctly elastic tumour, which bimanually proved to be uterine in origin. On October 18th, I removed the tumour by supravaginal hysterectomy. The operation was not a difficult one. She suffered severely from shock for a few hours, but at the end of twenty-four hours was distinctly improving, and has never gone back again. She got up two days ago and already feels much stronger. On section the tumour was found to contain numerous cavities, some larger and some smaller, which were filled with clear mucous semigelatinous fluid. He did not think it was malignant, and the clinical history did not point to it. After all, the clinical history was more important than the microscope. One usually thought that tumours of the uterus grew slowly. In this case the growth was rapid; the patient had no loss of flesh, and very little pain; she was well nourished and was blanched with hæmorrhage.

Dr. H. MACNAUGHTON-JONES said the first specimen particularly interested him because it was similar to one he had shown in that Society some time since. He understood the woman was a drinker, and perhaps had a cirrhotic liver which would account for the ascites. The second tumour looked like myxomatous degeneration of a fibroid, which had been classified as one of the forms of compound myoma with myxoma.

Dr. HEYWOOD SMITH would like to see microscopical sections of the deeper part of the tumour in order to determine whether the growth of a tumour like that absolutely destroyed all possibility of any further development of ova, as it seemed unusually dense; and also what relation it had to the former active life of the ovary.

Mr. CHARLES RYALL asked how much ascites was present. It was a curious thing that solid ovarian tumours were connected with ascites. Ascites was due to some irritant in the abdominal cavity, such as tuberculous peritonitis. It was a question whether it was due to the absence of any peritoneal covering.

Dr. S. JERVOIS AARONS said that the first specimen was like one removed at Soho Hospital about a fortnight ago, where there was considerable ascites. He was inclined to believe that the presence of a large solid mass was probably the irritant which caused ascites. He did not think it was only a concomitant of malignant tumours in the abdomen. He thought that a large solid mass which was more or less free could cause it. The second specimen had a peculiarly malignant appearance, and he hoped the Society might have an opportunity of seeing a section of it.

The PRESIDENT wished to know whether the liver had been examined. In his experience it was not common to get a large quantity of ascites with solid ovarian tumours.

Mr. J. FURNEAUX JORDAN, in reply, said he thought possibly the ascites might be due to the condition of the liver, but it appeared to be normal. He did not know what the cause of ascites was in a case like that. It was a mystery to him why there should be such an enormous quantity of fluid. There was no pressure on the vessels. He did not know where it came from. If it was desired, he would have a slide made from the interior of the tumour to see if the point raised by Dr. Heywood Smith was able to be cleared up or not. Although the woman had had sixteen children, he should not have thought of saying that her ovary was more active than any other ovary. The condition of the other ovary was perfectly normal. The reason he did not think the second tumour malignant was more from the clinical history and the appearance of the patient than from any microscopic report. He would, however, obtain a pathological report for the Society. He did not agree that this myxomatous condition was common. He had seen numerous specimens of fibroids of the uterus, but had never seen one like this before, and did not suppose that his experience was in any way exceptional. Of course, degeneration of one kind or another was common, but he did not agree that the form which he had presented was a common one.

Dr. J. H. SWANTON read notes on a specimen of

CYSTOMA OF OVARY.

with thyroid tissue present, which will be found on page 551.

Mr. CHARLES RYALL exhibited a specimen of

HYPERTROPHY OF THE VULVA AND CLITORIS.

occurring in an old syphilitic patient, with photographs. It was removed from a female, æt. 55, an in-patient of the Lock Hospital, under Mr. H. A. Shillitoe, who had kindly asked him to see her. On examination he found she had a hypertrophied condition of the vulva, with a peculiar hypertrophied pendulous condition of the clitoris. It was difficult to obtain a history. Her primary symptoms must have occurred years ago. She had a family, and the children were healthy. On

making an examination, the clitoris was found much elongated, and club-shaped. On one side it would be noticed that the labia were very much enlarged; there was a condition of pseudo-elephantiasis. All around the buttocks there was considerable induration, a condition which always indicated stricture of the rectum, and always one sort of stricture, namely, syphilitic stricture. The whole perineal region of the buttocks was a mass of inflammatory tissue, with openings all round from which pus oozed. The stricture of the rectum was not a very extensive one.

Above the stricture the bowel was quite healthy. He had the patient transferred to the Cancer Hospital. There she was photographed and the mass was removed. Microscopically it turned out to be a granuloma, evidently of syphilitic origin. He was not surprised at that, because at the Lock Hospital one came across a great many cases of hypertrophy of the vulva in old tertiary syphilitic patients, hypertrophy which very often became pedunculated, and it was not uncommon to find the clitoris enlarged and quite pendulous. In that particular case, the patient noticed the condition eleven years previously, but lately it had become very much worse, and there was a great pendulous mass hanging down between her legs, and on walking it got rubbed and became irritable and sensitive, so she was unable to take much outdoor exercise. It consisted of granulation tissue, partly chronic and some recent.

Mr. HARRY OVERY asked Mr. Ryall if he had found hypertrophy of the vulva associated with gonorrhœal discharge only. He had seen one case in which there was no evidence that one could find of syphilis, and the hypertrophy of the vulva was practically as large as a newly-born child's head. He wished to know whether Mr. Ryall had seen any cases in which syphilis was not a factor.

Mr. CHARLES RYALL said he had never seen hypertrophy of the vulva associated with gonorrhœa only, and where it existed would be suspicious that the patient had syphilis as well as gonorrhœa. He found that in the female syphilis failed to show the classical symptoms which one was accustomed to find in the male. For instance, it was very difficult in many of those cases to find the primary sore, and even if one found it, or if one came across extensive hypertrophy of the vulva—sometimes it was very extensive—that patient might not present the cutaneous symptoms which one was accustomed to find associated with the secondary stage of syphilis, nor did one find in the female that glandular enlargement which was also associated with the secondary stage of syphilis.

Dr. S. JERVOIS AARONS read notes on the

MEDICAL TREATMENT OF UTERINE HÆMORRHAGE,

which will be found on page 552.

In the discussion that followed,

The PRESIDENT said their thanks were due to Dr. Aarons for his excellent and interesting paper. He wished that the author had been more explicit as to the doses he had given, and how he employed the gelatine.

Mr. FURNEAUX JORDAN was really extremely grateful for the hints and advice which Dr. Aarons had given. The author's medical treatment of uterine hæmorrhage was very largely different from his own: he had relied upon ergotine and hydrastin. He had never heard of the treatment of injecting gelatine into the rectum.

Dr. MACNAUGHTON-JONES remarked that the difficulty in arriving at a solution of the problem as to whether one was to cure hæmorrhage by operation or by therapeutical means was the crux of the whole situation. He was glad to hear Dr. Aarons say that he had given those cases quite apart from any question of those forms of hæmorrhage which must be treated solely by operation. Many of the drugs which the author used, he had himself used. For some fifteen years or more he had been using hydrastin; he had used it in combination with stypticine and ergotine, and had generally found the combination to be very useful. Throughout the long list of cases given by the author he noticed that only on three occasions had he used the hot douche. He thought that that alone was a wonderful practical lesson. He did not know of anything which had been so abused in the past, and which possibly had done more mischief, than the hot douche used up to 120°, the patient being given her can to use *ad libitum*. He must confess that he was an advocate for curettage in most cases of hæmorrhage which did not quickly yield. One plan which he adopted had generally given him good results—the application of chromic acid in combination with curettage, from 30 to 40 grains of chromic acid to an ounce of water. In cases of endometritis that was a most valuable method of checking hæmorrhage.

Dr. HEYWOOD SMITH asked the author if he had found that stypticine had produced an increase of hæmorrhage. He had administered it to an unmarried woman who had had profuse menstruation from her earliest years, and it had produced it in still greater quantity. She had her last two periods every fortnight instead of every month. However, his impression was that a patient got wearied and did not persevere with it long enough.

Dr. BENNETT said the paper would be much more beneficial if one or two columns were added to it. They were given the condition of the patients, the cause, and the treatment, and the result, but they were not given the doses. He was speaking of those where drugs were used. It would also be of advantage if the time of treatment were put down, and the result, and how long a particular drug was continued before there was cure or improvement. In that way they would get the data for the consideration of whether medical treatment was superior to surgical treatment.

Dr. NEPEAN LONGRIDGE thanked the author for his excellent paper. In looking through the list of cases, he noticed Case 21, a woman, æt. 22, who suffered from menorrhagia with uterus infantilis. Surely that was a very unusual condition. Such patients suffered from amenorrhœa. He was not aware of the microscopical appearance of those uteri, but in his work in his hospital, he had seen many uteri of still-born fœtuses. He made sections from the uterus of every stillborn female child, and had been very much astonished in finding how extraordinarily vascular the uterus was. He would like to ask Dr. Aarons whether the uterus in a woman æt. 22 partook of those characteristics at all. There was one other criticism he wished to make. They were told that the cases were either cured or checked. What was the exact difference between a check and cure in a case of menorrhagia, because if a woman had menorrhagia there was not much difference between checking it and curing it.

Mr. CHARLES RYALL stated he found that rest was an important factor. The hæmorrhage was not cured, but it could be checked by rest alone. It was very interesting to note that the gelatine ought to be sterilised.

Dr. HODGSON said he had found on several occasions when the drugs which had been mentioned failed, that

tincture of cannabis, added to any of the other hæmostatics, would stop hæmorrhage almost magically. With regard to the hot douche, which Dr. Macnaughton-Jones had spoken of, he must say in some cases there had been sub-involution which had been curetted, and, assuming they were troublesome cases, he had used very hot water, much hotter than had been mentioned. He had used it at 135°, and had reduced the uterus two inches in size, and had never found any trouble afterwards—no pains or anything else, and scarcely any loss at all. With regard to nitric acid, that was a very useful drug, but one could not get it distributed in the interior of the uterus so well. It was better where one got a granular condition round the os. Another medicine sometimes used was solid nitrate of silver, 15 grains, but in his experience it was not successful.

The PRESIDENT said that the subject of the paper was uterine hæmorrhage, but the author did not state the cause of the hæmorrhage. He would ask Dr. Aarons whether he had examined the uterus, after he had treated the cases for a short time, and they had not responded to the treatment, for submucous fibroid or a tuberculous condition or anything of that kind, because if such conditions existed, no great benefit could be derived from drugs even if used for a very long time, or if there were benefit, he fancied that so soon as the patient began to get about again the hæmorrhage would probably recur. He would also like to know how long the author carried on his treatment; whether the patients were kept in bed the whole of the time; if, after leaving off the treatment for a few months, the hæmorrhage returned again; and whether there had been any return of hæmorrhage later on in life.

Dr. AARONS, in reply, said that with regard to hot douching, the only cases where he used it were cases of cellulitis, and even then it was not used with a view of reducing the hæmorrhage, but with a view of reducing the inflammatory conditions. He quite agreed that the hot douche had been vastly overdone, at all events so far as hæmorrhage was concerned. With regard to endometritis his impression was that most of it now was septic. In most of those cases it was better to try drugs first of all, and curette afterwards. He would rather try the effect of drugs before resorting to any operative treatment in a case of endometritis. He agreed with what had been said with reference to adenoma. He only discovered the patient had adenoma after treatment. She was a woman æt. 50, and her hæmorrhage was profuse. She had two or three periods after curetting, which were just as bad as before the curetting, and she reacted marvellously to the gelatine. There was another point about the case. She was æt. 50, and was probably near the menopause, and that might have had something to do with it. He had seen her afterwards when she had passed the menopause, and there had been no return. He thought adenoma was very closely related to carcinoma. With regard to stypticine, he had only used it on one or two occasions, but he saw no reason why it should increase the hæmorrhage. He could not answer that point. In reply to Dr. Bennett, he had mentioned the doses which he had given in the paper, except, of course, the hydrastin compound, which was a special formula. That was

HYDRASTIN CO. STYPTICIN.

Hydras Hydr.	¼ gr.
Ergotine	½ gr.
Cannabis Tan.	½ gr.
Stypticin	¼ gr.

Ergotine he had mentioned in the paper. He had also mentioned the gelatine — about 9 ozs. injected into the rectum. The patients were treated for three to six months. If they did not react in that time, then the uterus was examined. All those cases reacted. He had a great many cases of hæmorrhage, which, of course, were operated on at once; that was, they were not treated by drugs; but those were cases which he thought, from the clinical aspect, would react—cases of hæmorrhage after abortion where the uterus was empty. One often got subinvolution of the uterus, and there the compound which Dr. Macnaughton-Jones had suggested, of hydrastin, was one of the most valuable medicines. In reply to Dr. Longridge, the uterus infantilis was rather puzzling. The patient was sent to him first of all to know if she would probably become pregnant, as she wanted to be married. He said he thought it was extremely unlikely, with a uterus such as she had. Three or four months after that her doctor had sent for him again, saying that she was flooding. He could hardly believe it, but the doctor said, "There is no doubt about it; you must see her." He did so, and she *was* flooding. She had been in bed for the best part of six days and had used something like sixty diapers. He had not the remotest idea what the cause was, because he had not had a chance of examining the uterus, but it was probably constitutional. She had married since. He had not heard any more of her. With regard to the difference between check and cure, he had put down those cases as checked where it was kept under control while the drug was administered. In some of the cases the drug kept, not hæmorrhage, but the menorrhagia, within due limits. He had called those cases cures where, after taking the drug for three or four periods the patients had not required it again, and had normal periods without it. Some of the patients had rest. The cases of fibroid menorrhagia had rest. There again, menorrhagia with fibroid was a case for operation, but those were cases which were either operated on later, or refused operation. They were not treated medicinally with a view to avoid operation. He had only mentioned sterilisation of gelatine because he believed in two fatal cases at Guy's anthrax was found in the solution. But of course, if gelatine was used in that way, it was sterilised in the process of preparing it. He had used Cannabis indica, in the preparation which Dr. Macnaughton-Jones had mentioned. He had seen most of the cases after some four or five months, and these had remained practically free from hæmorrhage.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

President—HENRY R. SWANZY, P.R.C.S.I.
Sectional Secretary—E. H. TAYLOR, F.R.C.S.I.
MEETING HELD FRIDAY, NOVEMBER 2ND, 1906.
The PRESIDENT in the Chair.

EXHIBITION OF CASES AND SPECIMENS.

AFTER some introductory remarks by the President, there was an exhibition of cases and specimens.

Mr. J. L. KEEGAN exhibited a patient, æt. 78, upon whom he had performed the operation of suprapubic prostatectomy. He also exhibited a boy, æt. 7, whom he had trephined for intracranial abscess. *Resume* of case:—Boy, æt. 7, admitted into Jervis Street Hospital, April 26th, suffering from an extensive scalp wound caused by his having been knocked down by a tram. He had not lost consciousness. The wound was treated by resident staff, and sutured. Two days after this the scalp began to slough, and suppuration established itself in spite of free drainage. On May 13th, nearly three weeks after the accident, his temperature rose to 100°, pulse 115, and he was found in a convulsed condition. The first fit began by twitching of the facial muscles on the side opposite to the wound—viz., the left side; the left hand was contracted; left leg and arm in a clonic condition; patient unconscious. The fit lasted for about ten minutes, passing off, leaving patient pale and weak. Between May 14th and 16th he had three more fits, and had begun to lose power of the left arm and leg. On May 17th he had as many as fourteen seizures. On May 18th the scalp wound was opened, exposing the bone over the Rolandic area; it looked dry and yellow, evidently necrosed. A trephine was applied

over this area of bone, and as the instrument worked inwards pus welled up. On removal of the piece of bone a large collection of pus was evacuated; there was no pulsation in the area of brain substances exposed, but it was very tense. The tense dura mater was incised and a trocar passed downwards and inwards into the brain substance. Nothing escaped but a little blood. The cavity between the dura mater and bone was drained by strips of iodoform gauze. Temperature dropped from 102° to 100°, but, as he had two fits during the night, on the following morning more bone was removed with bone forceps and drainage continued. May 21st—Pulsation visible over affected area; no more fits; temperature 100°. May 21st to 27th—Normal temperature; no fits; patient improved so rapidly that he was allowed out of bed. June 8th—A large graft of skin was taken from the boy's thigh and applied over the raw surface; this took well, and completely covered in the brain substance. Present condition—There has not been any recurrence of the fits, all signs of paralysis in limbs have disappeared, and the brain is covered by a firm skin covering. The intracranial suppuration was evidently produced by a septic osteomyelitis secondary to suppuration in scalp. There was possibly a fissured fracture of the skull, through which the pus travelled, causing the intracranial abscess to form.

The case was discussed by Mr. R. C. B. MAUNSELL, who alluded to another case of a boy from whose skull a large part of the frontal bone had to be removed on account of severe injury. A large pulsating area remained after the healing process was completed, but no subsequent operation was undertaken, and no harm resulted. He would therefore advise against future intervention in Mr. Keegan's case.

Mr. ROBERT WOODS showed a case of a woman whose throat had been accidentally cut, fifteen months ago, through a motor car colliding with a tram car. All the tissues from the front of the neck to the vertebral column had been severed by the broken edge of a pane of glass. He had found, on examination, that a cicatricial diaphragm grew horizontally across the pharynx, behind the hyoid bone, shutting off the mouth and pharynx above from connection with the larynx and gullet below. Respiration was carried on through a tube inserted in the thyro-hyoid space, and feeding was only possible by removing the breathing tube and passing an œsophageal tube through the opening. A small opening, large enough to admit a fine probe, was found to exist in the centre of this diaphragm. The problem to be solved was how to enable the woman to speak so that she might carry on her occupation as a typewriter. Mr. Woods dilated the opening by a series of bougies till its diameter was sufficiently great to hold a tube through which she could breathe comfortably. This could not be put in without making some provision for the evacuation of the saliva, which was constantly trickling into her pharynx, and which, before she came under his care, lay in a pool over the pharyngeal diaphragm. Mr. Woods showed an apparatus by which he overcame these difficulties, and which consisted in a double tube, bent in the middle nearly to a right angle, so that it could be inserted through the thyro-hyoid opening and then upwards through the cicatricial diaphragm. The patient breathed through the large tube, while the smaller one was used for the purpose of sucking away the saliva by a suction apparatus attached to the patient's belt. The apparatus was found to work quite satisfactorily; the patient could talk, breathe and sleep very well, and was not in the least troubled by saliva trickling into her larynx.

The case was discussed by Sir ARTHUR CHANCE and Sir Kendal Franks, who was present as a visitor.

Mr. R. A. STONEY exhibited a case of malunited supra-malleolar fracture after operation. *Resume* of case:—Man, æt. 40, admitted to hospital last Christmas. He was thrown off a horse ten months previously and sustained a supra-malleolar fracture of both bones of the right leg. The bones had united in bad position, with outward displacement of the foot, causing great pain when the patient walked. At the operation callus was cut through, and the bones re-fractured. The foot was then brought into position and the tibia wired. Patient returned a month ago complaining of pain, on pressure, on the inner side of the leg above the ankle. This was found to be due to the wire, which was immediately under the skin. After removal of this the patient was able to walk perfectly without pain.

Mr. STONEY also exhibited a cancerous growth of the rectum removed from a man, æt. 60. It formed a large cauliflower-like mass, involving about three inches of the posterior wall of the rectum, and invading the region of the sphincters below. It was removed by the sacral route.

Mr. HAUGHTON, in discussing the case, enquired of what material the wire consisted, and why it caused trouble in Mr. Stoney's case. Great care was necessary in the sterilisation of wire employed for suturing bone, and it was his practice to keep it in the sterilising apparatus until required.

Mr. T. E. GORDON alluded to a similar case in which he had employed silver wire for suturing purposes. Subsequently it pressed against the skin, and had to be removed, but it was perfectly aseptic.

Mr. JAMESON JOHNSTON showed a case of a youth, æt. 18, who stated that he first noticed something wrong with his right hip about nine months ago, and which has been gradually getting worse. There never has been any pain in the hip, but the patient complains of pain in the inner side of the thigh and knee. At present there is some wasting of the thigh, the gluteal fold and trochanteric fossa are well marked; the great trochanter is displaced upwards at least two inches. There is some eversion and adduction; the thigh can be fully extended and almost completely fixed; adduction can be increased but abduction is impossible. These passive movements cause practically no pain. Skiagram shows a bending of the neck of the femur and the top of the great trochanter almost on a level with the acetabulum. Mr. Johnston considered the case to be one of coxa vara adolescentium,

Mr. MAUNSELL enquired if Mr. Johnston considered coxa vara as an entity in itself. It seemed to him either to result from tuberculous disease or rickets. It should not be regarded as a special disease.

Mr. EDWARD TAYLOR described a case under his care in Sir Patrick Dun's Hospital, which presented some features very similar to Mr. Johnston's. It was evidently tuberculous in nature. He had been very much interested in the skiagram of the hip-joint exhibited by Mr. Johnston. It gave him the impression that the head of the femur was partially dislocated.

Mr. HAUGHTON also discussed the case, and expressed the opinion that the head of the femur was partially dislocated upwards. Assuming this to be the case, the question arose, was the condition really coxa vara or erosion of the acetabulum as occurred in tuberculous disease.

Dr. EDWARD J. WATSON considered the hip condition the result of erosion of the acetabulum.

Mr. JAMESON JOHNSTON, in reply, stated that he merely employed the term coxa vara to signify a deformity. He found it difficult to associate tuberculosis with the case, as the boy had never had pain in the hip-joint.

Mr. HAUGHTON showed two patients in both of whom both femora had been fractured simultaneously. The first, a boy æt. 7, a year ago was pushed against a passing lorry, and both legs passed through the spokes of the wheel, and in this position rotated with the wheel. The right femur was broken in upper third (simple), and the left in lower third (compound). In addition, most of the ligaments of left knee were ruptured, and there were two compound fractures of left leg (both bones). Further, there was a severely lacerated wound two-thirds round leg just above ankle, almost amputating it, but circulation was present in

the toes, so the foot was spared. The boy can now run about vigorously, and stand on either leg alone, and has full motion in his knee-joints. (Skiagrams illustrating this case were handed round). The second case, a man, æt. 62, two years ago was wheeling a barrow of heavy stones from a sand-pit, when some tons of loose gravel and sand collapsed on him, crushing him to the ground. There were comminuted fractures of both femora in lower third, compound on left side, and rupture of internal lateral ligament of left knee. This man can now walk about strongly, and bear his full weight on either leg. His right femur was ununited three months after the accident. Torn muscle between fragments was diagnosed and verified by operation, when the ends of bones were chiselled into a concave and convex V, and a three-inch iron screw passed through them. Primary union by bone followed, and he still retains the screw *in situ*. The treatment in the two cases was similar. The limbs were scrubbed for twenty minutes with soap and hot water, followed by ether and alcohol (or biniodide in alcohol), and the compound wounds douched for twenty to thirty minutes with normal saline alone at body temperature, several gallons being used. Silkworm gut drains were then passed into all the wounds, and sterilised dressings applied. An anæsthetic (ether) was given, and plaster of Paris bandages at once applied from the toes to the axillæ, covering both legs and trunk, leaving a suitable cleft for urination and defæcation. During the plaster application, extension was maintained in the boy's case by Dr. Halahan's apparatus, and in the man's by a modification of Professor Kocher's. Mr. Haughton considered the good result obtained in each case to be due to—first, to a purely aseptic technique in dealing with internal parts of accidental compound wounds; and secondly, to the excellent fixation afforded by primary plaster of Paris, which methods are his routine practice.

Mr. Edward Taylor, in discussing Mr. Haughton's cases, stated that while he fully realised the excellent results which had been obtained, and for which Mr. Haughton deserved to be congratulated, it was a question whether the employment of plaster of Paris, as a rule, immediately after the occurrence of fracture was advisable. In Mr. Haughton's hands, and in the hands of other hospital surgeons, cases so treated had done well, but in the hands of less skilled individuals such treatment might be attended by considerable risk. His own practice was to place fractured limbs in splints for a few days before applying plaster of Paris.

Mr. Lentaigne expressed himself strongly in favour of the application of plaster immediately after the injury, and had made it a practice for years with most satisfactory results.

Mr. Johnston believed it was better to wait for the subsidence of swelling before applying plaster.

Mr. R. C. B. Maunsell exhibited three specimens of gastric carcinoma which had been excised.

Mr. W. Stevenson exhibited a necrosed humerus removed as a sequestrum, and a skiagram showing the sequestrum *in situ* before the operation.

Mr. Wheeler exhibited a loose body removed from the knee-joint.

Mr. W. Taylor exhibited a carcinoma of the cæcum and ascending colon which had been removed.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held November 7th.

The President, Dr. J. O. Affleck, in the Chair.

Dr. Allan Jamieson showed microscopic specimens of Darier's disease.

Drs. Alex. Bruce and Harvey Pirie showed microscopic specimens of the intermedio-lateral tract of the cord.

Dr. T. W. Dewar showed a case of lupus vulgaris of thirteen years' duration healed in forty days under treatment with hydrogen peroxide locally and intravenous injections of ethereal solution of iodoform. Very many methods of treatment had previously been tried, including a prolonged course of Finsen light. Koch's old Tuberculin had given a very marked reaction. The benefit received was ascribed rather to the injections of iodoform than to the local application of peroxide.

Dr. Allan Jamieson showed a case of Darier's disease in a woman. The bodies described as psorosperms had been discovered in microscopic sections of the skin, but their relation to the disease was doubtful.

Dr. Byrom Bramwell showed a male, æt. 42, suffering from ataxia to so marked a degree as at once to suggest tabes. Further examination, however, showed that the patient suffered from multiple sclerosis. The man was so ataxic that he could scarcely walk. He had no history of syphilis, no lightning pains, no loss of the pupillary light reflex. The knee jerks and achilles jerks were exaggerated, there was ankle clonus, double Babinski phenomenon, tremor, and nystagmus. The exaggeration of the tendon reflexes had diminished in degree during the past few months. The explanation offered was that in this case one of the patches of sclerosis was implicating a large area of the posterior columns in the lower part of the cord.

Dr. George Mackay showed two cases of hereditary optic atrophy. In both cases there was visual defect of several months' duration with changes in the optic discs and central scotoma. In one case a family history of blindness coming on in early adult life had been traced through three or more generations; in the other the patient's uncles had also been affected. The disease affected males chiefly, and was transmitted through the female line.

Dr. Edwin Bramwell showed a case of juvenile general paralysis in a boy of 16. The patient seemed to have been slightly backward before the onset of his present symptoms, which had originated eighteen months before after a fall on the head. They consisted in tremor, failure of memory, inco-ordination, loss of the light reflex, and exaggeration of the knee jerks. The tremor was well marked in the tongue and face muscles, and the speech was characteristically slurred. An interesting point was the absence of any history of congenital syphilis, or signs of it in the facies, teeth, eyes, &c., of the patient. Yet on examining the spinal fluid a marked lymphocytosis was present, which pointed to a probable syphilitic origin.

Mr. Stiles showed (1) a patient after enterectomy for perforated typhoid ulcer with diffuse peritonitis. The nature of the case was only ascertained at the operation, when the ileum was found to be perforated, and the thickened Peyer's patches were felt. About 6 ins. of bowel was resected, and a Paul's tube inserted. (2) A man suffering from multiple neuro-fibromatosis (Recklinghausen's disease). A large tumour had been removed from the buttock. This had been present as long as the patient could remember, while the smaller tumours scattered over the body had only developed, and were still developing, within a comparatively recent period. The tumours implicated the cutaneous nerves, not the main trunks. With two exceptions, which had been removed, they were painless. There was one tumour on the palm of the hand—a somewhat rare situation. (3) A case of complete facial paralysis following fracture of the base of the skull. Examination of the ear showed that in all probability the seat of the lesion was the temporal bone. As it was probable that the nerve had been completely torn across the Fallopian canal, and that new bone had been thrown out which would prevent reunion, Mr. Stiles thought the case a suitable one for transplanting the spinal accessory nerve on to the divided fascias. The slight paralysis of the trapezius which would follow would not interfere greatly with the usefulness of the arm (in this case the left), provided that the branches from the cervical nerves, and the nerves to the rhomboids were left undisturbed.

Dr. T. D. Luke exhibited Harvey Hilliard's new regulating chloroform inhaler, by which chloroform

vapour varying in concentration from ·75 to 4·5 per cent. can be administered. After a short account of the various apparatus which had been employed previously, he pointed out the advantages of the new pattern, and finally pleaded for the necessity of accurate dosage in using so active a drug as chloroform. Few students knew, he said, that 25 minims of chloroform evaporated was enough to produce anæsthesia. One great advantage of the inhaler over the drop method was that the administrator inhaled no chloroform. There was also no waste of the drug. With the inhaler he could induce anæsthesia in from four to six minutes.

Mr. ALEXIS THOMSON exhibited Roosevelt's clamp for gastro-intestinal anastomosis. It is, in effect, a double clamp, by which the stomach and bowel are approximated and held in a convenient position by a single instrument. The clamp is particularly useful when the mesentery is thickened and short, or where the cardiac part of the stomach has to be dealt with.

Drs. A. BRUCE and HARVEY PIRIE read a paper entitled

A PLEA FOR THE STUDY OF THE INTERMEDIO-LATERAL TRACT OF THE SPINAL CORD.

The paper was illustrated by a series of lantern slides, demonstrating the points raised in the paper, a full abstract of which will be found on page 550.

Dr. BYROM BRAMWELL congratulated Dr. Bruce on his work. The paper was one which would do much to stimulate interest. He thought it must now be regarded as almost proved conclusively that the intermedio-lateral tract was the centre for the sympathetic fibres. It was impossible to draw far-reaching conclusions from two cases, but it certainly was a remarkably striking coincidence that in both of these, lesions had been found by Dr. Bruce where from his previous researches he had anticipated them.

Prof. CUNNINGHAM discussed the paper from the anatomical point of view. He was now convinced that the tract must be regarded as the special centre for the efferent sympathetic fibres. Formerly, looking at it as an anatomist, he had been struck by the fact that the tract was, as it were, squeezed out of existence in the cervical and lumbar enlargements by the grey matter of the anterior horns. Now, he thought, its peculiar distribution could no longer be explained on this view, but corresponded with the distribution of the sympathetic fibres. He thought it would be admitted that Lockhart Clarke's work, done with imperfect methods, more than fifty years ago, had proved wonderfully accurate through the test of time.

The following were elected office-bearers for the ensuing year :—President : Dr. James Ormiston Affleck; Vice-Presidents : Dr. George Hunter, Prof. Greenfield, Dr. Byrom Bramwell ; Councillors : Prof. Chiene, Mr. Alexis Thomson, Dr. R. A. Fleming, Dr. F. D. Boyd, Prof. Harvey Littlejohn, Dr. Aitchison Robertson, Dr. Heppie Paterson, Mr. William Guy ; Treasurer : Mr. J. W. Dowden ; Secretaries : Dr. Lovell Gulland, and Mr. David Wallace ; Editor of Transactions : Dr. William Craig.

LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD THURSDAY, NOVEMBER 8TH, 1906.

The PRESIDENT, MR. FRANK T. PAUL, F.R.C.S., in the Chair.

DR. HUGH R. JONES read a note on

THE DEATH-RATE OF THE CENTRAL WARDS OF THE CITY OF LIVEROOOL.

He pointed out that, despite a large expenditure of money and the demolition of much insanitary property, and the building of many model dwellings, the death-rate of Scotland ward had not fallen as much as the death-rate of all England and Wales. The deaths of children under five years of age accounted for half the death-rate. Organised sanitation affected only early maturity. The density of population in Scotland ward was greater now than it was 15 years ago. He recommended the opening up of closed courts, the utilisation of school yards as playgrounds, &c., rather than a waste of public money on wholesale demolition. The landlord was to blame as well as the sanitary authority for not enforcing the wholesome provisions of the Housing Acts. He declined to discuss the social aspect, inasmuch as he believed the sanitary authority had a definite duty imposed upon it by the legislature.

After a few remarks on the subject by Dr. Wm. Carter and Dr. R. Caton,

Dr. F. W. PARKER YOUNG showed two patients who were under treatment for phthisis by the intravenous injection of formalin.

Dr. JOHN HAY, who had seen the cases before treatment, thought some improvement had taken place since he had last examined the patients.

THE RECENTLY DISCOVERED HEATLH TEMPLE OF HIPPOCRATES AT COS.

Dr. RICHARD CATON delivered a most interesting lecture on the above subject. The lecture was profusely illustrated by limelight views of the island, and of the recently excavated remains, and by plans and "reconstructions" of the ancient temple and sanatorium.

The lecturer said that the site, about two miles from the modern town of Cos, had been so changed by earthquakes, by the growth of vegetation, by the destructive work of the lime-burner, and by the erection in mediæval times of churches and mosques, that all traces of the magnificent Coan sanctuary had disappeared, and the association of the place with Asclepios had remained absolutely unknown for centuries. Prof. Rudolf Herzog, of Tubingen, began to investigate this site three years ago, and had been rewarded by the discovery of highly interesting remains of the ancient temple and precinct. To him and his fellow workers belonged the whole of the credit of the excavation. The temple precinct consisted of three terraces arranged in steps on the mountainside. A vast number of ancient earthenware pipes brought water to the baths and fountains, probably from the spring of Hippocrates, and from the celebrated red water, or iron spring, a couple of miles higher up in the mountains. The north side of the quadrangle contained many rooms, dispensary, library, and rooms for teaching purposes, for Cos was a medical school. About the centre of the second terrace there stood a huge altar, reminding the visitor of that of Pergamon, though on a smaller scale. This was interesting as being the scene of the fourth Mime of the Greek poet Horondas. The views from the temple commanding the mountains and plains of Cos, the blue Ægean, the islands and the hills of Asia Minor, were most striking. The sanctuary had no theatre or stadium, those of the town of Cos being easily accessible. The sacred grove of cypresses surrounded the upper part of the temple on three sides.

ULSTER MEDICAL SOCIETY.

THE annual dinner of this Society was held in the Medical Institute, Belfast, on Thursday evening, November 15th, the President, Dr. David Gaussen, in the chair. About sixty members were present, and the guests included Mr. Swanzy (President of the Royal College of Surgeons, Ireland), President Hamilton (Queen's College), Professor Schafer (Edinburgh), and Prof. Symington (President of the Ulster Branch British Medical Association). After the toast of "The King" had been honoured with the usual loyalty, the President proposed the toast of "The Lord Lieutenant and Prosperity to Ireland," coupling with it the name of Sir John Byers, whom he congratulated in the name of the Society on his recent honours.

The next toast was "The Irish Medical Schools," proposed by Dr. R. W. Leslie in a few well-chosen words, and responded to by Mr. Swanzy and Prof. Symington in speeches which gave rise to much interest and private discussion among the members. Mr. Swanzy, after disclaiming any right to speak for the Irish schools generally, took the opportunity of discussing the relation of the Belfast Medical School to Dublin, and specially to the College over which he presides. He had observed that the Belfast men who did not take the degrees of the Royal University

generally took a Scotch diploma, and he expressed a strong feeling that this was not as it should be, but that the Irish Colleges were worthy of the support of all Irishmen, and were not merely Dublin institutions. He said that he had heard various explanations, but nothing which he could call a reason, and begged them, if they knew of any difficulties or objections, to state them, so that they might be answered and met if possible. Prof. Symington, who followed, answered several of Mr. Swanzy's points. He said that the teachers of the Belfast School tried to get all their students to go for a University degree, and it was only those few who could not affordthe necessary time or expense who went up for the diploma of the Colleges. As regards any undue preference for Scotland, he pointed out that in the College calendar particulars were given first of the Royal University, then of the licensing bodies of Ireland, London and Scotland, in the order named, and he suggested that if the Irish Colleges wished to attract more Northern students they might do so by appointing a few more Northern examiners, as at present they had only one.

Prof. Sinclair proposed the toast of "Our Guests," with the names of President Hamilton and Professor Schafer, and referred to the successful efforts of the former in raising the "Better Equipment Fund" of Queen's College to £70,000. In replying, Dr. Hamilton said he wished to thank the medical men of Belfast for their most generous response to the appeals on behalf of the fund referred to, as he believed the generous example set by the medical graduates had much to do with the hearty support accorded to the fund by the lay public. Professor Schafer made the speech of the evening, and gave the members subject matter for thought for many a day to come. After referring to some recent researches on the influence of the pituitary body on diabetes insipidus—a subject-connected with that on which he had formerly addressed the Society, and which he wished to supplement, he plunged boldly into the stormy waters of the Irish University question, as it concerns the North. He expressed in the strongest manner his belief that the future evolution of the Belfast school must be on the lines of an autonomous university, with its own degrees, its own examiners, and its own standards. Why, he asked, should not Belfast have its own university as well as Leeds, Sheffield, and Birmingham? He knew that there were difficulties, religious and political, in the way, but difficulties were made to be overcome, and if we wanted a university we should get it. His remarks were received with enthusiasm by a small section of his audience, who were delighted at this independent support for their generally unpopular ideals. The majority, howeve, listened in respectful silence, as they still cling to the teaching of the late Dr. McKeown, the founder of the Royal University Graduates' Association, who dreaded an Ulster University lest his pet bogey of Denominationalism should find a home in it, and who had a touching faith in the possibility of improving the Royal University so as to make it a thoroughly satisfactory institution.

"The President and Secretary of the Ulster Medical Society" was proposed by Dr. McKisack, and responded to by those gentlemen. During the evening songs and recitations were given by Drs. McKenzie, MacIlwaine, Calwell and Morrow.

Sciatica.

Years ago the treatment of sciatica by injections of medicinal agents was recommended by Luton (1863), who employed morphia and even nitrate of silver. Since then numerous authors: George, See, Dieulafoy, Albert Robin, injected in the neighbourhood of the sciatic nerve solutions of antipyrine, methylene blue, phenic acid, chloroform, distilled water, concentrated solutions of the glycerophosphates, etc.

Within the last few years, M. Lannois employs systematically subcutaneous injections of artificial serum over the painful points, the liquid, to which is added two drachms of sulphate of soda per quart, is injected warm in drachm doses every two days.

M. Barthelemy, of Nantes, follows the same practice but with larger doses (5 drachms), and makes three injections at one sitting: the first as deep as possible at the point of emergence of the nerve, the second, behind and below the great trochanter, also deep, and the third more superficial in the postero-external region of the thigh. The two first injections are perfectly painless, but the third smarts a little. No tissue swelling nor rubefaction is observed after the injections.

The patient complains at first of a sensation of numbness in the limb for the first two or three hours after the injections, when it disappears giving place to a marked sensation of relief and the improvement is such that the patient returns for a renewal of the treatment. M. Barthelemy repeats the injections every ten days, but sees no reason not to renew them more frequently. He thinks also that sea water might take the place of the ordinary artificial serum.

Several authors have published cases of successful treatment by injections of cocaine into the medullary canal in the lumbar region, but this treatment is not always easy for the general practitioner and is not without a certain amount of danger, while the serum injections are inoffensive and frequently effect a cure.

The surgical treatment consists in the stretching of the nerve, which had been practised for years, but to-day more or less abandoned. M. Pers reports two successful cases from simple exposure of the nerve. He made an incision between the great trochanter and the tuberosity of the ischium. As soon as the nerve was found he isolated it, and examined it to see if it had retained its normal white colour, and was not fixed by adhesions. In both cases the nerve was red and fixed. The incision was prolonged until the nerve was found white and free. The red colour was due to conjunctive tissue which enveloped it. The covering was detached and the nerve resumed its normal aspect.

The simple method of exposing the nerve (neurolysis) is claimed by M. Pers as superior to the classical forcible stretching by which its fibres are ruptured.

GERMANY.

Berlin, Nov. 18th, 1906

Substitution of Great Toe for Lost Thumb.

At the last meeting of the Medizinische Gesellenschaft Dr. Krause showed a young man for whom a great toe had been substituted for a thumb. The thumb had been lost in an accident, and only about 1.5 cm. of the stump of the bone left. The patient was very much handicapped in his work through the loss. After the proposal of Nicoladini, who had made use of the second toe, which was atrophied and useless for the purpose, Krause proposed to utilise the great toe of the patient. Treating very carefully and sparingly the cicatrix over the end of the bone, and preparing it, he made a transverse section on the dorsal aspect of the great toe at the level of the interphalangeal joint, and to gain space, resected a piece from the basal phalanx, sutured the skin and extensor tendons of the thumb to the corresponding parts of the great toe, and fixed the whole in plaster of Paris, keeping the parts in this position for seventeen days. At first the pain caused by the strained posture was very great, especially in the knee, but it was relieved by morphia. Everything was then well borne, but the heat was much complained of. (This was in July.) At the end of the seventeen days the plantar side of the toe was cut through and fixed to the thumb. The result was excellent. The patient

had a useful movable thumb with which he could grasp and hold firmly.

Herr Stabel showed a young man who twenty-seven days before had undergone whilst at his work very severe pressure over his abdomen. Immediately after subconjunctival hæmorrhage took place, the remains of which were still visible. There were also extravasations of blood under the skin of the forehead, the cheeks, and neck.

Exz. von Bergmann showed a man with

SARCOMA OF THE NOSE.

As much as ten years ago he had had small tumours removed from the nose repeatedly. A big operation, apparently resection of the upper jaw, was done five years ago. The patient had now a large disfiguring tumour on the forehead and base of the nose which forced the eyes apart, and was a sarcoma. Herr Exz. considered it indispensable in retropharyngeal tumours to make the field of operation as open to view as possible, and did not hesitate in such cases to resect both upper jaws, and, beside this, to pull the nose high up, so as to obtain a wide entrance to the nasopharyngeal space.

Herr Gluck had operated on the patient five years before, doing a resection of the upper jaw. The patient was free from recurrence for two years. Then it returned, but he declined further operation until the tumour had reached its present dimensions.

AUSTRIA.

Vienna, Nov. 20th, 1906.

DOUBLE PLASTIC OPERATION TO CRANIUM.

CLAIRMONT showed a patient from Eiselsberg's ward on whom two plastic operations in the cranium were performed at one sitting. A young man, æt. 19, fell from a wall sixteen metres high, on June 6th, and received a complicated fracture of the skull. In hospital two depressed fractured bones were removed. After three days' unconsciousness, paralysis of the right arm, alexia, agraphia paraphasia, and amnesia were observed to be present. Two months later all the soft tissues of the head had healed and the patient was dismissed.

He returned to hospital about the end of September with two defects in the cranium, one in the left parietal bone, the other in the occipital on the left side. Both were covered with soft tissue, depressed and pulsating, arterially and with every respiration. When he stooped he became giddy. At this time there was paresis on the right side of the face, but he was able to spell very well, but read badly.

On September 22, Morphine-chloroform narcosis was effected and an operation commenced to cover both defects with bone, although the patient objected before narcosis to have the bone taken from the tibia. After opening the cicatrices and laying bare the dura mater, the edges of the wound were freshened and a piece of the neighbouring bone with periosteum brought over the wound after Hacker-Durante's method. After fixing with fine catgut the whole was covered with soft tissue. Over this again was placed a perforated celluloid plate to which the soft under-tissue was attached to prevent sinking. There is no pulsation to be seen; the patient can stoop without giddiness, with less paralysis, and more freedom of speech.

LEAD POISONING.

Zappart showed two cases of lead poisoning in girls engaged in handling and finishing French ties. A few years ago he drew attention to the same subject, and found the chronic cases still increasing in number. The silk of these ties is finished with a solution of the sugar of lead, which is dry and dusty when it comes into the workshop for the girls. Their hands, clothes, and hair become impregnated with the poisonous substance, while the air they breathe all day is loaded with poison. This work is often carried to the homes of the workers, where they sleep, eat, and drink, poisoning slowly whole families.

ELECTRIC INJURIES.

Teleky showed photographs from a worker in an electric works, where the current had passed to earth along a bar of iron he held in his hand, injuring the little finger, which the current struck with a force of 110 volts as he accidentally touched the machine. On the back of the little finger there was a wound about the size of a sixpence, at the point of entrance, and another on the inside of the finger one centimetre long and two millimetres in breadth. This confirmed Jellinek's assertion that injuries from electric currents were deeper and more extensive than they appeared, and were therefore longer in healing. The photos of this case, taken eighteen days after the injury, showed the wounds larger than on the day of accident, particularly that on the inside of the finger, *i.e.*, the point of exit of the current.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

BELFAST.

MEDICAL STUDENTS' ASSOCIATION: ADDRESS BY PROFESSOR SCHAFER.—The inaugural meeting of the session of the Belfast Medical Students' Association was held in the Students' Union, Queen's College, on Wednesday, the 14th inst. The President of the Association, Dr. W. J. Leighton, read a paper on "Quacks and Quackery," urging the necessity for Government interference in the matter. Professor Schafer then gave an address on "Resuscitation of the Apparently Dead." He said that his subject was of interest not only from a scientific, but also from a humanitarian and utilitarian point of view. Dealing first with the result of an overdose of chloroform, he said that he knew of no means of resuscitation in such cases, and the best thing to do was to avoid them. He then dealt with the resuscitation of the apparently drowned, and described Dr. Marshall Hall's method, which he called the rolling method, and Dr. Silvester's, or the method of artificial respiration, and Dr. Howard's or the American method. Professor Schafer then gave several tests of artificial respiration by a method which he had demonstrated to be most effective and simple. the prone pressure method. The patient is placed face downwards and pressure is exerted on the lower portion of the ribs, by which air is forced out of the lungs, and when pressure is released there is a corresponding inhalation. The method was explained by lantern diagrams, and illustrated by a subsequent demonstration, and for simplicity and lucidity the whole address was a model for scientific lecturers. On the motion of President Hamilton, seconded by Professor Milroy, and supported by Sir Otto Jaffe, a hearty vote of thanks was accorded to Professor Schafer.

LONDONDERRY CORPORATION AND CONSUMPTION.—The Medical Officer of Health for the city of Derry, Dr. J. H. Fergusson, has started a movement which may have far-reaching results in the North-West of Ireland. In a very full and admirable report presented last week to the corporation, he dealt at length with the prevalence of consumption, and the means to be taken for its suppression. He proposed that a small and influential committee should be appointed to consider the whole matter, and to enter into negotiations with the neighbouring counties with a view to the establishment of sanatoriums. The report is at present under consideration, and it is to be hoped the suggestions in it will be acted upon.

LETTERS TO THE EDITOR.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to a letter in your issue of November 7th, headed "Great Ormond Street Hospital for Sick Children," and signed "Observer," and I should like with your permission to reply, in order to remove from the mind of your

correspondent one or two misapprehensions, which might possibly find their way into the minds of the readers of his letter.

First, this hospital does not provide for its own neighbourhood only. Considerably less than half of its out-patients are drawn from Holborn, Finsbury, St. Pancras, Islington, and the City, the Boroughs which immediately surround it. The remaining patients, the greater half, if the expression may be allowed —come from all over London and its outskirts, since the central position of the hospital, close to the intersection of High Holborn and Kingsway, allows it to be reached easily and economically from every quarter of greater London. For a tram fare of 2d. a working man's wife and her small child can travel from the remotest point of the East End of London almost to the doors of the hospital. Thus the hospital provides for thosewhom "Observer" considers the "more capable" parents who live outside Central London. But at the same time it must be remembered that many of those inhabiting Central London are not slum-dwellers, as he supposes, but equally capable workmen compelled to live near their work.

Secondly, as to the danger of spread of infection from the congregation of large numbers of children in the out-patient department, special precautions are taken to prevent this. Nurses are stationed close to the entrance of the out-patient doors, who divert into isolation rooms children suffering from infectious diseases or in whose homes there may be infection. Crowded our waiting rooms may sometimes be, but steps are being taken to obviate this by building a new out-patient department which will be finished in about eighteen months' time.

Next, let me say that our chronic cases are already, and have been for the last thirty years, removed to a better atmosphere and healthier surroundings than those of Bloomsbury. We have a branch hospital at Highgate, which holds 30 beds in winter, and 38 in summer. These are filled with chronic cases, for the most part surgical. In addition, two convalescent homes, one in Hampshire and one in Gloucester among the hills, containing eighteen beds between them, are placed by the kindness of friends exclusively at the disposal of the hospital, while the Samaritan Fund helps many more patients to convalescent homes in the country and at the seaside. On the other hand, the air of Bloomsbury is very much healthier than perhaps "Observer" imagines. At the hospital in Great Ormond Street our surgical wards have spacious balconies on which tuberculous cases are able to remain in the open air day and night both winter and summer, with results that it would be difficult to surpass even by treatment in the country or at the seaside.

As regards the ills which arise from bad sanitation and high temperature, there can be no doubt that the most effectual way to combat them is to clear away the unhealthy courts and alleys, where so many London children still have the misfortune to be born and reared, and the hospital views with sympathy all efforts to bring this about. But the process is and must necessarily be a slow one, and in the meantime infective diarrhœa will continue to carry off its annual crop of victims for many summers to come. Consequently it behoves the hospital authorities to do what they can to mitigate the evil, and this they have endeavoured to do by devoting a special ward to these cases, and extra beds in each of the medical wards; some thirty beds in all.

It is true that this is a very small number compared with the number that are carried off every summer week in London by diarrhœa and vomiting, but is it not better to save some lives rather than abandon all to the fate which almost certainly overtakes them if they are allowed to remain in their own homes with only out-patient or dispensary treatment. But over and above this, the devotion of a special ward to these cases enables observations to be made both as to the cause and treatment of the disease which may prove of the greatest value in the future. During the last two years, while the physician in charge of the ward has been investigating the disease from the clinical aspect, the Lister Institute has been carrying on a bacteriological investigation. The results of last year's work in both departments have been published in the medical papers, the results of this year's will be made public in due course, I have no doubt, through the same channels. The students attending the medical school attached to the hospital have already had the advantage of learning them.

I am, Sir, yours truly,

STEWART JOHNSON, Secretary.

November 13th, 1906.

ANTI-VIVISECTION METHODS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—A brief record of the following incident seems worth making. In the *Tribune* of November 8th, there appeared a paragraph headed, "Inspector's Admissions at the Commission." It stated that Mr. Thane, in course of examination, described an operation on a cat by Mr. Starling. "The scalp was skinned off, the skull itself sawn through, and the bone removed, leaving a part of the brain exposed. Electrical needles were driven into the brain, and fixed there by modelling wax. Mr. Starling then thrust a hollow needle through the side of the eyeball into the interior of the eye, and fixed it. The ganglion (*sic*) was then excited by means of the electric needles, and the effect produced on the eye observed and noticed. The cat, Mr. Starling stated, was anæsthetised, but Mr. Thane admitted that it jumped down off the table." On the following day, November 9th, the *Tribune* gave prominence to a statement that their report was untrue, that no such evidence had been given before the Commission, and that they "had been victimised." The grotesque narrative reads like an account of the nightmare of an anti-vivisectionist fanatic, and would have been looked upon with grave suspicion by any one having the slightest knowledge of the methods of experimental physiologists. No doubt the statement has been scattered far and wide among the votaries of the cult; and the lies will not easily be caught up by the withdrawal and the "frank apology" which the *Tribune* makes to the libelled gentlemen whose names it made use of. The *Tribune* is a paper which sets itself up as a pattern in conduct among its contemporaries; this episode is not likely to increase respect for the paper among thoughtful and educated readers.

I am, Sir, yours truly,

PHYSIOLOGIST.

November 17th, 1906.

OBITUARY.

DR. M. O'SULLIVAN, F.R.C.S.

WE regret to record the death of Dr. Michael O'Sullivan, late of 14, Gardiner's Place, Dublin. He qualified in the Royal University in 1892, and became a Fellow of the Royal College of Surgeons, Ireland, in 1900. For twelve years he was intimately connected with the Mater Misericordiæ Hospital, first as resident surgeon, and then as anæsthetist and registrar. For some years previous to his illness he acted as chief physician to the Children's Hospital, Temple Street, but it was to anæsthetics that he devoted a special study. At the time he was seized by an incurable nerve affection, he was commanding an extensive practice.

GENERAL SAMPSON ROCH, R.A.M.C., M.R.C.S.E.

DEPUTY SURGEON-GENERAL SAMPSON ROCH, whose death, at the age of 77, occurred on the 9th inst., at Yougal, Ireland, entered the Army as an assistant surgeon in 1854. He served with the 55th Regiment through the Crimea, including the siege of Sevastopol, and on June 7th accompanied the French in their assault upon the Mamelon. He received the meda

and clasp for the Crimea and Turkish decoration. He retired as a surgeon-general in 1881.

DEPUTY SURGEON-GENERAL J. WILES, M.R.C.S., L.S.A.

WE regret to announce the death of Deputy Surgeon-General Julius Wiles, of De Vere Gardens, Kensington, who was knocked down while cycling on November 10th by a van and died the same afternoon from the injuries he received. The inquest showed that the horses attached to the van had taken fright at a motor-car. Surgeon-General Wiles, who was seventy-eight years of age, had served long and faithfully in the Army Medical Department, which he entered more than fifty years ago.

JOHN GEORGE DOUGLAS KERR, M.B., C.M. GLASG.

WE regret to announce the death of Mr. John George Douglas Kerr, M.B., C.M., on the 14th inst., at Bath. Mr. Kerr at Glasgow University won the double medal in surgery in 1878, and became Master of Surgery two years later. Upon going to Bath he made a special study of the hot mineral waters, to which he published a guide. He was also the author of a number of works associated with thermal treatment. Mr. Kerr held a number of honorary professional appointments, including that of medical referee of the Royal National Hospital for Consumption, Ventnor. He was a magistrate for Somerset, and served for many years as an officer of the North Somerset Yeomanry. Mr. Kerr was an enthusiastic yachtsman, and, with "Valdora," gained, among many other important prizes, the German Emperor's Cup for the Dover to Heligoland race in 1894, and last year the Albert Cup at Southsea

ARTHUR CROSSLEY, M.R.C.S., L.R.C.P.LOND.

THE death took place at Uckfield, Sussex, on the 12th inst., of Mr. Arthur Crossley, son of the late Dr. Crossley, of Leicester, in his forty-fifth year. The deceased gentleman left Leicester about twelve years ago to practise in Eastbourne, and afterwards removed to Uckfield. He was educated professionally at Guy's Hospital, and qualified M.R.C.S. of England in 1880.

JAMES C. RATTRAY, M.D.EDIN.

THE news was received in Swindon last week with genuine regret by a very large circle of acquaintances of the death of Dr. James Carson Rattray, a well-known local medical practitioner. Dr. Rattray had long been a sufferer from an abdominal complaint, but it was hoped that an entire change and absolute rest would restore him to good health. He went to Scotland some few months ago, and died at Aberdeen on Tuesday. Deceased, who was only forty-two years of age, came to Swindon eighteen years ago, and commenced practice. The deceased gentleman was held in high esteem throughout the town and district. He graduated M.B., C.M. of Edinburgh University in 1888 and M.D. in 1889.

SPECIAL ARTICLE.

ROYAL COLLEGE OF SURGEONS OF ENGLAND—ANNUAL MEETING.

AT the Annual Meeting of Fellows and Members of the College on Thursday last (Mr. Henry Morris, President, in the chair), there were present fifty members and twenty-three Fellows. The President placed before the meeting the annual report of the Council, and made a statement regarding the more important matters which had come under the consideration of the Council. He also stated that copies of the Report had been circulated to 684 Fellows and 3,036 Members, who had expressed the wish to have their names entered on the standing list at the college for the Report to be sent to them annually.

Direct Representation.—The question of direct representation of members of the College on the Council has always been to the fore at these annual meetings, and on this occasion Mr. Joseph Smith moved the following resolution, which was seconded by Sir Charles Hutchinson, ex-M.P. for the Rye Division of Sussex, and carried by forty votes to three: "That this twenty-second annual meeting of Fellows and Members again re-affirms the desirability of admitting members to direct representation on the Council, which as now constituted does not represent the whole Corporation."

The Admission of Women.—Dr. W. G. Dickinson then moved the following resolution which was seconded by Mr. J. Brindley James: "That this meeting recommends that, when the question of admitting women to the college examinations is brought before the Fellows and Members, this should be done either by means of a Corporate Meeting or by a poll of the Fellows and Members, inasmuch as the Meetings as hitherto held under the regulations of the Council have no authority to determine any question whatever, and their resolutions on other subjects are almost invariably disregarded by the Council." An amendment was moved to this by Mr. F. G. Parsons and seconded by Mr. A. D. Cowburn, that the words "either" and "or by a poll of the Fellows and Members" be omitted. This was not carried, but, upon the original motion being put to the meeting, another amendment was moved by Dr. A. S. Morton and seconded by Surgeon-Major Ince, that the words "either by means of a Corporate Meeting or" be omitted, and this was carried. The following resolution was thereupon put and carried: "That this meeting recommends that when the question of admitting women to the College examinations is brought before the Fellows and Members, this should be done by means of a poll of the Fellows and Members."

The Midwives Act.—With reference to the Midwives Act, a resolution standing in the name of Dr. A. S. Morton, of which due notice had been given, was not put to the meeting, as the mover accepted the chairman's assurance that the Council was desirous of making representations to the Government urging the necessity of amending the Midwives Act, in order that provision might be made to secure just remuneration for professional services rendered by medical men under that Act.

Preliminary Education.—The following resolution, moved by Mr. George Brown and seconded by Mr. George Jackson, was also slightly altered from that which appeared on the agenda, and was carried by twelve votes to two: "That this meeting strongly urges the Council to use all its influence to secure the raising of the standard of the preliminary examinations in general education and in science, and this meeting is further of opinion that the time has arrived when chemistry, physics, and biology should be treated as matters of preliminary education, and an examination passed in them before the commencement of medical studies."

A vote of thanks to the Chairman for presiding, coupled with congratulations to the ex-president, Sir John Tweedy, on receiving the recent honour of knighthood, terminated the proceedings.

The Kensington General Hospital.

H.R.H. the Princess of Wales has graciously given her patronage, and is showing a kindly interest in the entertainment to be given at the Scala Theatre on the evenings of December 11th, 12th, and 13th, in aid of the Kensington General Hospital, and T.R.H. the Prince and Princess Alexander of Teck have also given their names. This hospital, which has been so completely reorganised and generally reconstructed in every way, both in regard to its Board of Management and its medical and surgical staff, is urgently in need of funds. Few people realise that it is the only hospital in the district, and that nothing in the way of medical attendance for out-patients in this big district can be found nearer than the West London Hospita at Hammersmith, and St. George's Hospital.

MEDICAL NEWS IN BRIEF.

Session of the General Medical Council.

THE Registrar of the General Medical Council requests us to state that the next Session of the Council will open on Tuesday next, November 27th, at 2 o'clock p.m., the President, Dr. Donald MacAlister being in the Chair.

The Irish Medical Association—Special General Meeting.

A VERY largely attended meeting of the Irish Medical Association was held on Wednesday last at the Royal College of Surgeons, to consider the attitude which the Association should adopt towards the report of the Commission on Poor-law Reform, and especially towards that part of it which recommended the institution of a State Medical Service. The meeting was the largest held for many years, and testified to the great interest which the proposed change in the Poor-law Medical Service excited. Unwisely, we think, it was held in private, but, doubtless in a short time all due publicity will be given to its deliberations. In view, however, of the fact that the resolutions were practically unanimously adopted, the Association would have been wiser in giving the result of its deliberations more clearly and explicitly to the press.

The following resolutions were adopted by a very large majority:—

(1) Proposed by Dr. Warnock, seconded by Dr. Thompson, ex-M.P., "That we, the members of the Irish Medical Association, offer our congratulations to the members of the Viceregal Commission on Poor-law Reform in Ireland upon the production of their able report and upon the broad and statesmanlike view that they have taken of the subject, and that the Council of this Association be directed to urge upon the Government the importance of giving effect in the main to the recommendations contained in this report with as little delay as possible; and that in any reform the members of the Poor-law Medical Service and those of the County Infirmary Service should form a homogeneous State service, and be in all respects dealt with in a similar manner."

(2) Proposed by Dr. O'Carroll, seconded by Dr. Singleton Darling, "That this meeting of the Irish Medical Association is strongly of opinion that any body or Council administering the Poor-law Medical Service should contain a majority of members elected periodically from among the members of the profession practising in Ireland."

(3) Proposed by Dr. Magennis, seconded by Dr. Powell, "That all Hospitals and Infirmaries under the contemplated reformed Poor-law Service should be designated by a uniform title."

London Street Noises—Conference of Medical Men.

SIR THEODORE MARTIN, President of the Street Noise Abatement Committee, occupied the chair, on the 12th inst., at a conference of the Medical Society of London to consider the noise problem of the metropolis. He complained that the authorities had been perfectly apathetic in dealing with the question. He described motor omnibuses as "awful machines," and himself as "a victim to the misery inflicted" by them. The Chief Commissioner had made the most extraordinary admission ever made by a public official. He admitted he had the power to stop these Juggernaut cars; but he had not stopped them. The reason he gave was that he wanted an experiment made in the new kind of locomotion. In his (Sir Theodore's) house he could not open a window owing to the stench caused by these vehicles. in bed he was badly shaken; double windows were no protection to him; the ceilings were all cracking. Many of his friends resident in London streets with long leases were being tortured and slowly killed due to the experiment of the Chief Commissioner. The old motto, *Salus populi suprema lex*, no longer had any force.

A resolution was moved by Sir Dyce Duckworth as follows: "This conference of medical men desires to record its conviction that the present excess of noise in the public thoroughfares of London is such as to cause disastrous consequences to the health and vitality of the people, and that legislation in respect to the growing evil of street noises is urgently needed, and should be promoted without delay." He was of opinion that no language could exaggerate the nuisance caused by motor-cars. Their noise and stench were grievously affecting the health of the community.

A second resolution called for legislation to prevent all street shouting, organ-grinding, and street music; for the effective supervision and control as to speed and otherwise of all classes of vehicles; and for the entire prohibition of noisy traffic through purely residential streets at least between midnight and six in the morning.

The resolutions were carried unanimously.

Cork Medical and Surgical Society, Annual Dinner.

THE annual dinner of this Society was held on the 10th inst. under the presidency of Professor C. Y. Pearson, and was most successful. A large number of members and guests were present. After the toast of "The King" had been duly honoured, the president proposed the toast of "The Cork Medical School," coupling with it the names of Professor H. Corby and Dr. J. Cotter. In replying both speakers referred to the successes of Cork students as illustrated by recent achievements. Colonel McNeece, R.A.M.C., replied to the toast of "The Navy and the Army," and in the course of his speech pointed out that the Director-General and the two assistant directors of the Royal Army Medical Corps are Irishmen. Colonel J. Crofts, I.M.S. (retired) also replied.

The Welcome Research Laboratories and Vivisection.

In reply to Mr. G. Greenwood, who asked on the 16th inst. if, as the result of the inquiries promised, he can now say whether vivisectional experiments are habitually performed at Gordon College Khartum, in the Wellcome Research Laboratories, or elsewhere; whether the Gordon College, though not under the control of the Foreign Office, is in any way subject to British control; whether the Wellcome Research Laboratories form part of such college, or what is their connection with it; how such laboratories are maintained, and whether or not by public money; and whether operators in such laboratories or otherwise at the Gordon College are subject to any inspection, regulation, or control, Sir E. Grey says: No vivisectional experiments in the ordinary sense of the term are conducted at the Wellcome Research Laboratories, but from time to time painless hypodermic inoculations have been given to living animals in order to further the diagnosis and cure of the obscure tropical diseases to which men and animals are exposed when living in the Sudan, and many valuable results have been obtained. The Gordon College is under an executive committee and trustees appointed under the Gordon College at Khartum Act, 1899. The research laboratories, the equipment of which was given by Mr. Henry S. Wellcome to the Sudan Government, are affiliated to the Gordon College. The maintenance of these laboratories is a charge upon the Gordon College, the revenue of which is derived partly from an endowment and partly from a grant made annually by the Sudan Government. The laboratories are constantly visited by several members of the Sudan Governor-General's Central Sanitary Board.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS. ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE.

Bladder Affections in Gynæcological Cases.—Grad (*Amer. Jour. of Obst.*, September, 1906). Besides the classical cases of cystitis, the writer calls attention to a form of bladder affection, which, for want of a better term, is named cystitis, and in which many of the subjective and objective symptoms of true cystitis are lacking. In these cases the desire to urinate is intense and very frequent. The patient is tormented night and day with the imperative desire to urinate, and in many cases this is the only subjective symptom present. Palpation does not reveal a tender organ, and the urine is clear and acid in reaction. Epithelial cells and pus are absent. This form of bladder disturbance occurs in the young as well as the old, and is usually due to exposure. Cystoscopic examination reveals an intensely congested tissue, very tender to touch, and the mucous membrane bleeds very readily. The tiny arterioles are intensely congested, and appear to be in danger of rupturing. The temperature is normal, rarely elevated. The treatment of these cases is at times quite problematical, as the therapeutic measures prove very ineffective. The writer has found most success in these rebellious cases from the intravesical instillation of adrenalin chloride, diluting the full strength of the preparation about two-thirds. Though the effect of this on the vesical vessels is only temporary, yet the patient experiences a considerable amount of relief, and after a little initial burning, pain is relieved while the urgency to urination is lessened. F.

Artificial Renal Colic as a Means of Diagnosis.—Hutchins (*Amer. Jour. of Obst. and Gyn.*, September, 1906), continues a report of the investigations in 100 cases of obscure pain in the side, by a method introduced by Howard Kelly. The method consists of the production of an artificial renal colic by forced injections of the renal pelvis. The method of producing an artificial distension of the pelvis of the kidney in order to reproduce or to rule out certain symptoms which may be referable to disease of this organ, consists of catheterising the ureter and passing the eye of the catheter gently up to the pelvis of the kidney; allow patient to rest awhile in a comfortable position, and then inject slowly by means of a glass barrelled syringe of 15 cc. capacity, a solution of methylene blue heated to body temperature. By this means fluid is carefully forced into the pelvis of the kidney until the patient begins to feel pain, and without hesitation states whether this is or is not the same pain as that of which she complains when at home. If the pain is the same then it must be of renal origin; if the pain is definitely not the same, then we can rule out the kidney as a cause, and search for trouble elsewhere. The confusion which is often present between the pain caused by pelvic disease or disease of the vermiform appendix and that of renal origin is shown by a report of 23 cases, in all of which pain was present which might easily have been referred to some trouble situated in the kidney or ureter. F.

Diagnosis of Extra-Uterine Gestation by Rontgen Rays.—Lichtenstein (*Med. Woch.*, March, 1906). The writer considers that an X-ray examination should always be made in cases of abdominal tumour in women where the possibility of advanced extra-uterine gestation cannot be precluded with absolute certainty from the clinical examination alone. In advanced extra-uterine gestation the fœtal parts and the lie of the child are observed on X-ray examination much more plainly than in uterine gestation on account of the thinness of the fœtal sac, the smaller amount of amniotic fluid, and the non-interference of the uterine walls and placenta with the rays. F.

Rupture of the Vagina in Labour.—Hellier, Leeds (*British Medical Journal*, October 6th, 1906), under this heading relates the history of a case. The patient, a 7-para, fell into labour on a Friday afternoon, a midwife being in attendance. During the night and the following morning the labours were said to have been "fairly strong, but not out of the way." At 1 p.m. on Saturday afternoon the pains ceased, and the patient complained of pain in the left hypochondrium. There were, however, no marked symptoms present. The midwife sought the assistance of a doctor, who, at 3.30 p.m., found the head on the perineum, and, applying forceps, easily extracted the child, a full term male. Having delivered, the placenta followed in due course, with no undue hæmorrhage. It was then found that a portion of the omentum was lying in the vagina. This was pushed up. Dr. Hellier was seen in consultation about forty-eight hours after delivery, and found the patient suffering from sepsis of moderate severity. There were no signs of general peritonitis, and the lochia were not excessive or fœtid. On making a vaginal examination, he found a mass of tumefied omentum with a loop of intestine lying above. The hand passed through the vaginal wall. The tear was from the posterior edge of the cervix. The omentum transverse and large, the vaginal wall being torn away and bowels were pushed through the rent, and the vaginal wall sutured to the posterior wall of cervix, and gauze packing introduced on either side of the wound. The condition of the patient became worse, however, and death followed in about twenty-four hours. Having given some statistics and references, Dr. Hellier quotes Freund as to the cause, who holds that in rupture of the uterus there is usually a fixing of the lower uterine segment, as by the cervical wall being nipped between the presenting part and the bone, or by some rigidity or cicatricial condition of the parts, but when the cervix is free to dilate it is the vagina that ruptures under the given conditions, and not the uterus. H.

Nitrite of Amyl in the Treatment of Post-Partum Hæmorrhage. — Keith, Driffield (*British Medical Journal*, Oct. 27th, 1906), reports a case in which he considers the use of this drug was followed by desirable results. The patient was a 4-para, æt. 33, with a history of bad post-partum hæmorrhage after her previous confinement. During her pregnancy she was in a poor state of health, and badly nourished. The labour was normal until after the third stage was completed, when profuse flooding commenced. An inhalation of a capsule of amyl nitrite was administered, and the hæmorrhage was almost immediately arrested. Two pints of saline were given by the rectum, and her pulse, which was 120, soon improved, and in less than one hour was 86. No further trouble followed. H.

Abdominal Hysterectomy for Inversion of the Uterus, Fatty Degeneration of the Inverted Portion.—Barbour, Edinburgh (*Journal of Obstetrics and Gynæcology of the British Empire*, October, 1906).—The author mentions the fact that while changes in the mucous membrane of the inverted uterus have been fully described, he can find no references to changes occurring in the muscular wall. The patient, a 3-para, was admitted to hospital two months subsequent to her confinement, which had been instrumentally terminated, as had her previous two, with all three children stillborn. She

had lost a considerable amount of blood, but the puerperium as far as she felt was uneventful, save that she could not pass her water for the first three days, and it was not drawn off until the third day. The doctor told her then that her "womb was down," but she noticed nothing herself. Six weeks later she was told her "womb was inside out." Still she was in no way troubled, and felt nothing specially wrong. On vaginal examination a mass the size of a golf ball was felt, smooth and round; no cervix was felt. Under anæsthesia the absence of the fundus on bimanual examination, and the inability to pass a sound up alongside the mass, proved the condition. An attempt at reduction was made by fixing the organ and endeavouring to push the fundus up, but this failed. A week later the abdomen was opened, and the posterior rim of the cup-shaped depression was incised through both thicknesses of the uterine wall. Pressure was again exerted from the vagina, and the incision continued posteriorly until the inversion was undone. There was inconsiderable hæmorrhage. The uterus was now seen to be undergoing marked fatty degeneration, so a supra-vaginal amputation of the organ was performed. Microscopically examined, the mucous membrane on the exposed surface of the uterus was entirely absent, its place being taken by a condensed fibrous layer. The muscle fibres underneath this were degenerated; below this, again, there was an area of healthy fibres, and then, nearer the peritoneum, the fibres had undergone fatty degeneration, until immediately below the peritoneum their place was taken by fat. The author advocates the abdominal route as enabling the operator to obtain a better view of the parts, and the condition of the organ after reduction.

H.

The Reaction of Vaginal Secretion.—Investigations which are being made by Bengelsdorff, of Helsingfors (*Archiv. f. Gynäk*, Bd. 78, Hft. 3) concerning the vaginal secretion of pregnant and lying-in women, have suggested also an examination of the vaginal secretion of newly-born infants concerning which investigators differ in important points. The author examined at intervals of twenty-four hours the secretion of vulva and vagina obtained by means of a Pasteur's pipette fitted with an aspirator. The tables which he gives concerning twenty cases show that the vaginal secretion of the child immediately after birth may be alkaline, neutral, or more rarely acid. After a few hours or days it becomes altered, and is always acid. Bacteria take no part in this change, because it occurred in cases in which no bacteria could be found. In two cases in which the opening in the hymen was very small, closely surrounded by the labia minora, and covered over with vernix caseosa, the reaction immediately after birth was acid. The author concludes, therefore, that the vaginal secretion generated in utero is acid, and only becomes neutral or alkaline from entrance of the acid liquor amnii by diffusion or the movements of the child. When bacteria were found they were most usually the bacillus coli and the staphylococcus albus. Döderlein's vaginal bacillus could not be found by the author immediately after birth in any of the cases. It does not appear, therefore, to take any part in the production of the acidity during the first days of life.

G.

The Effect of Rontgen Rays on the Ovaries.—The microscopical appearance of the ovaries of rabbits after they have been subjected to the Röntgen rays is described by Specht (*Archiv f. Gynäk*, Bd. 78, Hft. 3). As Halberstädter has already demonstrated, a complete disappearance of the Graffian follicles occurs in the majority of cases, and the primary follicles, much diminished in number, showed distinct signs of degeneration. In addition, Specht observed that in the greater part of the interstitial substance of the ovary the cells were much smaller and much poorer in protoplasm on the rayed side than on the other. Through this discovery, the diminution in size of the ovary which has been rayed in comparison with the other may be completely explained. In order to recognise the very first signs of degeneration, the author, at different intervals, removed ovaries which had been subjected to the rays for one to two hours. At periods varying from 12 to 24 hours alterations were already to be found in the primary follicles and interstitial tissue, which were in all probability due to the action of the rays. If a method should be discovered by which the sensitive human skin could be protected from injury by the rays, the latter might take the place of some operative measures now in use.

G.

Chronic Oophoritis and the Physiological Variations in the Structure of the Normal Ovary.—Theilhaber and Meier (*Archiv f. Gynäk*, Bd. 78, Hft. 3) hold that the clinical symptoms, tenderness, size, consistence, shape, etc., do not prove the presence of chronic oophoritis. Theilhaber also considers that the usual anatomical conditions given in the literature, thickened albuginea hyperplasia of the connective tissue, diminution of the follicles, alterations in the walls of the blood-vessels, are not at all pathognomonic. The ovaries of 86 women, 69 of whom had no gynæcological disease, were examined by Meier. The results of his difficult and extremely interesting investigations demonstrate very great variations, physiologically, in the structure of the normal ovary, among them being diffuse thickenings of the albuginea, increasing diminution in the number of Graffian follicles as age advances, hypertrophy of the connective tissue, and alterations in the walls of the blood vessels. Arteriosclerosis is not characteristic of chronic oophoritis, neither is hyaline degeneration of the vessel walls. Accumulations of large numbers of small round cells are frequently found in the neighbourhood of not too old corpora lutea. True oophoritis only exists in connection with salpingitis. In these cases one frequently finds thick scar-like bands of connective tissue crowding deeply into the parenchyma and completely taking its place. Cystic degeneration is also found. Theilhaber does not believe that idiopathic chronic oophoritis exists. In those cases in which it is diagnosed on account of localised tenderness, one is generally either dealing with the neurosis which may coincidently be combined with the presence of an unusually large ovary, or we have the remains of a salpingo-oophoritis.

G.

Puerperal Infection.—Hellendahl, Tübingen (*Beiträge zur Geb. und Gyn*, Bd. 10, Hft. 2) considers in this the second part of his investigations the effect of infected liquor amnii on the mother and child. He established by experiment that penetration of the intact membranes by virulent bacteria is quite possible. They extend upwards between the uterine wall and membranes, and force themselves through the membranes into the liquor amnii. They may also extend from the peritoneum through the tubes. Infection of the liquor amnii extending from the blood-vessels of the uterine wall only plays a subordinate part in comparison to the infection extending through the placenta. The latter is a most important path of infection. The fœtus may be infected from sucking in the liquor amnii owing to premature attempts to breathe, or from spontaneous entrance of the bacteria into the body openings. In cases of general infection of the fœtus, it usually has its primary focus in the lungs. Owing to intra-amniotic infection the fœtus may die in utero or post partum. The latter is caused either by a pure bacterial broncho-pneumonia or by general sepsis associated with broncho-pneumonia. A general infection extending from the intestinal tract is also possible. For the mother the most important cause of fever intra partum is premature rupture of the membranes; but it may also arise when the membranes are intact. A prognosis regarding the puerperium cannot be made from the height of the fever during parturition.

Irish Medical Schools and Graduates Association.

THE autumn dinner of the Irish Medical Schools' and Graduates' Association will take place at the Hotel Great Central, Marylebone Road, London, N.W., on Wednesday, November 28th, at 7.30 p.m. The guest of the Association will be Admiral Sir Edward Seymour, G.C.B., O.M. Tickets can be obtained by members of the Association from Mr. E. Canny Ryall, 85 Harley Street, W.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

R. S. (Ipswich).—A good alkaline tooth-powder is :—

Pulv. Iridis	- -	dr. s.
Ol. Cinnamomi	- -	m. iij
Mag. Carb. Pond.	- }	aa dr. iv.
Cretæ Precip.	- }	
Misce.		

A. S. T.—The idea that flies take part in the propagation of disease is not as new as you, and probably many others, think. Ambroise Paré mentions as his opinion that flies certainly tend to disseminate plague. Vide Œuvres Complètes, 1575. Book X., Chap. VI.

DR. P.—The earliest observations in this country were, we believe, those of Schäfer and Oliver. But there have been many published observations on the physiological action of suprarenal glands since.

PLEXUS.—Your informant is right. We do not greatly admire the new phraseology, but the word autosite is regularly used to denote a monstrosity capable of independent existence.

DESMOND.—The patient clearly belongs to A, but if he wishes to change there is no ethical reason why he should not go to you.

TWEED.—We are interested to hear that the St. Andrew's Ambulance Association is now working in England. Mr. L. Darlington, of 5 Kirkgate, Bradford, is the honorary secretary of the Bradford centre. If that town is in your neighbourhood, you had better apply to him.

L. D. (Bradford).—Thank you for your letter. Please see answer to Tweed.

THE TENURE OF POST-OFFICE SURGEONCIES.

A CORRESPONDENT writes to ask the date on which the age limit of Post-office Surgeoncies was brought before the attention of the House of Commons. At the moment of going to press we have not the exact reference to hand, but it can be readily found by looking through a list of questions asked in the House during the ten days or so prior to our issue of the 14th of November.

NURSE W. H. H.—We are obliged for your letter, and for the facts you bring to our notice. There is no doubt, we believe, that there was a general and most unfortunate misunderstanding. There should be no prejudice now that all is made clear.

STAMFORD.—The death-rates for the three towns mentioned are :—21·4, 46·3, and 51·8 per 1,000 respectively. The plague naturally accounts for much.

MEDICO.—The recent Order *re* certificates of instruction in vaccination was issued on December 20th, 1905. It applies to medical men qualified on or after May 1st, 1906, and to them only.

G. P. (Wells).—Arterio-sclerosis most commonly occurs in elderly persons of the male sex, who have had syphilis or who have indulged in alcohol to excess.

RESPICE FINEM.—The fees for medical evidence in the High Court vary. Of course if a witness, being a medical man, gives evidence as an ordinary, and not as a professional witness, he cannot claim more than the ordinary witnesses are paid. On the other hand, the fees of experts are generally a matter of arrangement with the solicitors and parties by whom they are summoned.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 21st.

ROYAL MICROSCOPICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Paper :—Mr. J. W. Gordon: The Use of a Top Stop for Developing Latent Powers of the Microscope.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. M. White: Clinique. (Surgical.) 5.15 p.m.: Lecture :—Dr. A. Morison: Disorders of Cardiac Motion, their Nature and Treatment.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. F. Taylor: Medicine. 3.15 p.m.: Mr. M. Robson: Surgery. 4 p.m.: Mr. Cargill: Ophthalmology. Out-patient Demonstration :—10 a.m. Surgical and Medical. 11 a.m.: Eye.

THURSDAY, NOVEMBER 22nd.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture :—Dr. A. Morison: Disorders of Cardiac Motion, their Nature and Treatment.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture :—Dr. M. Dockrell: Acne Vulgaris in its Three Stages: I., Comedo; II., Indurata III., Necrotica.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Mount Vernon Hospital, Hampstead).—5 p.m.: Demonstration: Dr. J. E. Squire: Cases of Chest Disease.

FRIDAY, NOVEMBER 23rd.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m.: Special General Meeting *re* Amalgamation of Medical Societies. Papers :—Dr. J. W. Carr: A Case of Hæmorrhage into the Frontal Lobes of the Brain.—Dr. J. Fawcett: Acute Peritonitis with Fat Necrosis apart from Disease of the Pancreas. Mr. W. G. Spencer: Cystic Dilatation of the Lower End of the Ureter, containing Calculi which became engaged Intermittently in the Urethra.

BRITISH ELECTROTHERAPEUTIC SOCIETY (11 Chandos Street, Cavendish Square, W.).—8 p.m. Council. 8.30 p.m. Discussion on the Report of the Organising Committee for the Union of Medical Societies of London (opened by Dr. H. L. Jones). Paper :—Dr. G. H. Graham: Notes of an Unusual Fracture of the Fifth Metatarsal Bone (illustrated by a radiograph). Demonstration :—Dr. D. Baynes: New Form of Electrical Apparatus.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Mr. M. Yearsley. Clinique. (Throat.)

Vacancies.

Aberystwyth Infirmary and Cardiganshire General Hospital.—House Surgeon and Secretary. Salary £150 per annum, with board and residence. Applications to R. T. Edwards.

Bethlem Hospital. Two Resident House Physicians. Salary £25 each per quarter. Applications to the Treasurer, Bridewell Hospital, New Bridge Street, E.C. (See advt.)

Newcastle-on-Tyne Union.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, rations, and washing. Applications to James Atkinson, Clerk to the Guardians, Union Offices, Pilgrim Street, Newcastle-on-Tyne.

Brentford Union.—Assistant Medical Superintendent. Salary £120 per annum, with furnished apartments in the Infirmary, rations, and washing, &c. Applications to William Stephens, Clerk to the Guardians, Union Offices, Isleworth.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140 per annum. Applications to the Medical Superintendent.

St. Mary's Hospital, Paddington, W.—Resident Casualty House Surgeon. Salary £100 per annum, with board and lodging. Applications to Thomas Ryan, Secretary.

Bristol General Hospital.—Senior House Surgeon. Salary £150 per annum, with board, residence, &c. Applications to the Secretary.

Durham County Council.—Inspector of Midwives and Health Visitor.—Salary £120 per annum, with travelling expenses. Applications to T. Eustace Hill, County Medical Officer of Health, Shire Hall Durham.

Northampton.—Saint Andrew's Hospital for Mental Diseases.—Third Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

Appointments.

COX, A., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Gateshead District of the county of Durham.

CRAFTON, W. M., M.B., B.S.R.U.I., Certifying Surgeon under the Factory and Workshop Act for the Sutton Bridge District of the county of Lincoln.

DRINKWATER, R., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Medical Officer of Health by the Llangollen Rural District Council.

HUNTER, D. G., M.B., Ch.B.Glasg., House Surgeon to the Durham County Hospital.

JOYNES, FRANCIS JAMES, M.R.C.S., L.S.A., Medical Officer of Health for the Dursley (Gloucestershire) Rural District Council.

LAING, A. W., M.B., Ch.B.Aberd., House Surgeon to the Birmingham and Midland Ear and Throat Hospital.

Births.

CHARNOCK SMITH.—On Nov. 17th, at Steyning, Sussex, the wife of C. Charnock Smith, M.R.C.S., &c., of a daughter.

MANSELL.—On Nov. 12th, at 278 Portland Road, Woodside South Norwood, the wife of A. R. Mansell, L.R.C.P., &c., of a daughter.

Marriages.

BURTON—LEAF.—On Nov. 15th, at Immanuel Church, Streatham Common, Arthur Burton, M.D., of Cromer, the youngest son of the late Edward Frederick Burton, of 15 Cleveland Gardens, London, to Olive Clare Leaf, the youngest daughter of the late Frederick H. Leaf, of Streatham Common.

MARSHALL—COOKE.—On Nov. 14th, at Aldridge Parish Church, Alfred Turner Marshall, B.A., son of the late Rev. Alfred Marshall and Mrs. Marshall (Wigston), to Matilda Rachel Cooke, youngest daughter of the late William Harry Cooke, M.D., and Mrs. Cooke, Aldridge.

SANDERSON-WELLS—LAWRIE.—On Nov. 14th, at St. John's Church, Weymouth, Thomas Henry Sanderson-Wells, M.D.Lond., eldest son of John Septimus Wells, of Banbury, to Agnes Macpherson (Nan), eldest daughter of Dr. James Macpherson Lawrie J.P. D.L., of Greenhill, Weymouth.

Deaths.

MARRACK.—On Nov. 15th, at Caer-Eden House, Lyonsdown, New Barnet, Jessie, wife of Richard Marrack, of Lincoln's Inn, barrister-at-law, and daughter of the late John Gregory Forbes, F.R.C.S., aged 56.

NORTON.—On Nov. 17, at 63 Upper Gloucester Place, London, George Everitt Norton, M.R.C.S.

SANKEY.—On Nov. 16th, at Boreatton Park, Baschurch, Salop, Mary Ann, widow of W. H. O. Sankey, M.D., F.R.C.P., aged 86.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, NOVEMBER 28, 1906. No. 22

NOTES AND COMMENTS.

Professional Differences.

ONE hears *ad nauseam* of doctors differing; indeed, the cant phrase embodying the idea always makes an effective hit when suggested by a barrister in difficulties, or a journalist in search of an argument. But such is the majesty of law that the conflicting opinions of judges are looked upon as inevitable sequelæ to high legal learning, and instead of each of the disputants being written down as a fool, he is regarded as either a Titan or an Olympian. Far be it from us to detract from the dignity of the Bench, but we may say that our own respect for it has not been distinctly enhanced by reading some remarks of Deputy-Judge Layman at the Southwark County Court, with regard to an application for a new trial made to him in the case of Hathaway *v.* Peers earlier in the month. The plaintiff in the suit had complained of negligent treatment in her confinement, and in spite of the expert testimony of a well-known obstetrician, who said that the case had been skilfully conducted, the jury had awarded her £25 damages.

Judge versus Jury.

IT was known, however, that the jury were divided in opinion, and the defendant by his counsel subsequently appealed for a new trial. Deputy-Judge Layman, nevertheless, said that he could not grant one, as the issue had been presented to the jury and decided by them, and he could not see how it was possible to say that it was so unreasonable that he could set it aside. But in justice to the defendant, he added that he might say that if he himself had had to determine the matter, he would unquestionably have found for him. Here is a clear case in which a lawyer trained in the sorting and weighing of evidence finds "unquestionably" that the verdict was against the evidence, and therefore by a natural process of reasoning grossly unjust; yet he is unable to grant a new trial. The plain man can only conclude that a process of law so defective merits the contempt of the community.

The Sublime Port.

AN epidemic of scarlet fever lately took place on the "Arethusa," a training ship moored in the Thames where lads are prepared for the mercantile marine. Of the two hundred boys on the ship, no less than fifty-one caught the disease, and one died. Dr. Hubert Williams, medical officer to the Port of London, in reporting to his Authority, said that it early became obvious that if the outbreak were to be stayed, a large number of the lads should be treated as contacts, but that means of isolation were practically non-existent, because the available hospital accommodation was soon used up by those already sick. Now this question of providing adequate accommodation has, it appears, several times been before the Port Sanitary Committee, but that body in its wisdom does not think it "reasonable" that it should be called on to do so. And why not, indeed? The purpose for which sanitary authorities are armed with powers is that they may use them for the benefit of those whom they govern, and though it may be most unreasonable for epidemics to break out, it is a way epidemics have. The reasonableness of the Port Sanitary Authority would be a little sweeter if it realised its full responsibilities.

Consumptive Boycott.

BUT reasonableness is a hard quality to cultivate. In a recent issue of the *Daily Graphic* was recorded an interview with the honorary secretary of the National Association for the Prevention of Tuberculosis, in which that gentleman deplored the fact that it is difficult for a "cured" consumptive to get employment. "Their fellow-workers object to them, fearing infection—without any ground, of course, because even if not entirely cured, the patients have been taught to exercise every precaution. It is a great pity this, and very sad." The fact is indisputable, but as the National Association for the Prevention of Tuberculosis is the body which, more than any other agency, taught people that consumption is infectious, it is not without humour that the secretary should complain that people have learned the lesson too well. The real lesson, it seems to us, is that owing to the natural density of the human brain, societies in a hurry are apt to do almost as much harm as good.

Lombroso Spiritualised.

THE Spiritualists deserve felicitation on their latest convert. Professor Lombroso is a man who bears a great name, and though his enthusiasm is not always well directed it has carried him through many difficulties to a high position in the scientific world. He lately wrote an article in *La Lettura* relating his favourable impressions of a spiritualistic *séance*, and though a scientist has replied in another journal stating that the phenomena observed were

produced by trickery, the great criminologist has replied with conviction that he adheres to his beliefs. After relating the various tests he applied, such as surrounding the mediums with an electric net provided with bells which would ring on the least movement, Lombroso asks what further proof could be required. We should say that the evidence that would convert a hard-headed man with the acuity of a Huxley, and the technical knowledge of a Maskelyne, would be good enough for anybody, but that Spiritualism has more worlds to conquer than that inhabited by the genial, soft-hearted enthusiast which it has just captured. In this country, at any rate, we have heard considerably less of the Spiritual impostures of late years.

LEADING ARTICLES.

SOCIALISM AND MEDICINE.

The process of "intelligent anticipation" is one which has a great fascination for all people, from Mr. H. G. Wells to the least imaginative policeman that paces his measured beat, and as long as a forecast is based on reasonable probability it is not without utility. Now the prophets of the day were all set agog by the result of the election at the beginning of the year especially by the return to Parliament of a band of Labour members, and from speculations on the effect of Protectionist measures on the country they have now turned their minds to the prospects of Socialism. If we read them aright they see in the not far distant future the complete triumph of collectivist principles, with national land and national labourers, national railways and national engine-drivers, national mines and national miners. Well, that may be so, and we should only join the ranks of the prophets if we expressed the opinion that it would not. Two great arguments stand in the way: first, that such a change would be a triumph of rationalism, and if rationalism turned out such a dismal fiasco in France, its chances in England must be less than nil; and secondly, that the person who imagines the free-born Briton is going to be municipalised into an automaton must read history strangely. But without straying into purely political issues it may with some confidence be predicted that the rôle of the State in communal life is likely to follow yet further the course it has steadily been taking for the last fifty years, namely, that of assuming larger responsibilities towards the individual than the old-fashioned Radical would have contentedly allowed. It is almost startling to recall the fact that Bright and Cobden and their followers were bitterly opposed to the Factory Acts, measures whose beneficence is gratefully acknowledged by men of all shades of opinion to-day. The Factory Acts, however, were only an early instalment of a number of Acts of repressive tendency of which the compulsory Vaccination Acts, the several Public Health Acts and their amending Acts, the Food and Drugs Act, and a dozen such, are notable examples. If, then, this process of care for the individual is to develop at the rate it has been developing of late years, is it within the horizon of practical politics that doctors themselves as guardians of the individual health and welfare will be co-opted by the State? We are moved to these thoughts by the odd coincidence that lately, side by side with the report of the Poor-Law Commissioners for Ireland recommending the institution of a State Medical Service, there appeared in the *Labour Leader* an article sketching out the lines of a Socialistic Medical Service. The writer in that journal, himself a medical man, proposed that the country should be mapped out in medical parishes on the lines of ecclesiastical parishes, and that to each 8,000 rural inhabitants or 10,000 urban ones three medical practitioners should be appointed for attendance in illness. Each district should be in touch with a centre where not only would a hospital be available for serious cases, but also a specialist staff, any member of which the local doctor could summon for consultation when desired. On the plan proposed every general practitioner would carry the stethoscope of a consultant in his top-hat, so to speak, and if he showed a tendency to specialise he would be granted study facilities for the purpose he had in view. An interesting part of the scheme is that at each centre there would be well-equipped laboratories for research purposes, staffed by men who had shown aptitude for the work. Moreover, every practitioner should have a course of four weeks' post-graduate study every year at a hospital centre to keep himself abreast with the advance of his profession. The whole service should be based on competitive examination, and promotion likewise should be determined by that test. At first sight this scheme seems inviting enough, but how far, it may well be wondered, would it be a remedy for present discontents between the profession and the public? A State Medical Service for the poor in Ireland has long passed beyond the stage of being a desideratum; it is a crying necessity, and unless the recommendations of the Commission under that head be put into practice, it is difficult to see how the guardians are to obtain skilled medical aid for their paupers. But it is a far cry from a State Service for State protégés to making the public with its own money in its pocket employ the doctor detailed to their district whether they like him or not. The public want a doctor whom they like, know, and trust, and medical men want patients who have confidence in them. These ends are attained by free competition and not by Government regulations. Moreover, the very name "medical research" stinks in the nostrils of the Socialistic party, and it may be taken for granted that no laboratories, and consequently no scientific advance, would be sanctioned under their régime. Finally, one would soon find all the grievances of contract practice blazing out with redoubled energy, and on reflection we think it better to bear the ills we have than to fly to others that we know not of.

PHYSICAL DIAGNOSIS.

THE medical art is eminently scientific, inasmuch as it is founded on reasoned methods of investigation. Every advance is the result of the discovery of fresh facts, either by greater accuracy of observation or by the inclusion of novel machinery in the shape of some newly-born ancillary science. Take, for instance, bacteriology. The merely curious and interesting researches and speculations of Pasteur in one generation have in another simply revolutionised the whole attitude of mankind towards disease as one small portion of his environment. In a less degree radiography may be cited as a second example. The accurate investigations of Sir William Crookes into the phenomena of electrical discharges in high vacuum have led to such important things as wireless telegraphy and the art of Röntgen-ray diagnosis. The latter method adds greatly to the resources of the physician, and still more to those of the surgeon by enabling him to investigate many physical conditions hitherto wholly or partly inaccessible. Indeed, physical diagnosis may be described as the revealing of objective symptoms by special methods of investigation. The development of this branch of semeiology was admirably sketched by the illustrious French physician, Professor Potain, in an article published in the issue of THE MEDICAL PRESS AND CIRCULAR of November 7th. He pointed out that our forefathers in the art knew practically nothing of physical semeiology, which occupied an insignificant place in the art of the physician who was not capable of elucidating them. The modern observer, however, is in possession of a great variety of methods of exploration, and the study of physical signs has accordingly acquired an immense and extended importance. One of the essential foundations of his work has been a knowledge of the main facts of pathological anatomy. The absence of that information among the ancients, owing to the fact that dissection of the dead was not permitted, may account for their non-discovery of auscultation and percussion. As Professor Potain remarks, it is no exaggeration that Laennec founded a new science, which he practically created in the space of two years at the beginning of the nineteenth century. The hundred years that have elapsed since the introduction of the stethoscope mark but a short period in the progress of medical science. In spite of much that has been achieved, a great deal remains to be accomplished before physical diagnosis can be regarded as nearly approaching the level of an exact science. That proposition, indeed, requires to be at once qualified by the addition of the limitation of the method to accessible organs, for it is hardly possible to imagine routine methods of ascertaining the intimate objective conditions of such inaccessible regions as the brain and spinal cord. But even in well-recognised and readily accessible positions the most experienced physician is liable at times to go astray. In such cases the usual physical signs may be non-recognisable or misleading. Professor Potain, in the article above-mentioned, discusses these insidious cases under the term "latent diseases." As an illustration he mentions a patient who was under his care in 1894 for rheumatic endocarditis, which left apparently only a slight affection of the mitral valve. Ten years later she was admitted with pronounced cardiac hypertrophy, which could not be explained by so slight a mitral lesion. The patient died of heart failure, and *post mortem* the explanation was found in the shape of an extensive obliterating pericarditis, which had determined the cardiac dilatation, but which had escaped detection during life. Among the latent diseases that most readily escape our observation, the writer cites cerebral tumours, cancer of the kidney, cardiac symphysis, ulcer of the stomach, and renal calculus. It is interesting to reflect, however, how much light can be thrown upon these particular conditions by the ophthalmoscope, the microscope, chemical analysis, exploratory incision and radiography respectively. There are still many obscurities in physiology and pathology, the clearing up of which may at any moment put us in possession of new or improved means of physical exploration. Electricity, for instance, offers a well-nigh inexhaustible set of problems. At the same time it may be pretty confidently assumed that the cultivation of the clinical faculty will always be an essential of first importance to the success of the physician.

NOTES ON CURRENT TOPICS.

A University for Munster.

THE generous offer recently made by Mr. William O'Brien, M.P., to leave his entire fortune as a contribution to endow a university for the province of Munster has added a new interest to the proceedings of the Royal Commission on Trinity College, Dublin, and also has caused considerable surmise as to the attitude which will be adopted by the Roman Catholic hierarchy towards Mr. O'Brien's scheme. It is obvious that if the latter means anything it means the establishment of a "mixed" university, and as the hierarchy have explicitly declared against any such institution it is difficult to see how they can support Mr. O'Brien's scheme. Mr. O'Brien made his most generous offer at a public meeting held in Cork, and he further said that he would immediately provide the sum of £50,000, if the Borough Council and County Councils of the province were willing to assume a small temporary burden. This would provide an income of £10,000 a year for five years, and if to it was added the present endowment of £10,000 a year and the private benefactions which would undoubtedly be given by Cork citizens, there would be sufficient to enable a start to be made without appealing to the State for a farthing. Mr. O'Brien was further of opinion that the scheme of

the president of the Queen's College for altering the constitution of the College had the consent of many members of the Cabinet. Several resolutions were passed by the meeting approving of Mr. O'Brien's proposals, and recording the opinion that a separate and independent university should be created for Munster, with its seat in Cork.

Medical Men and the Public.

Signs are not wanting that the public is beginning to recognise that, taking it all round, the medical profession is overworked and underpaid. The man in the street, however, is not likely to permit so faithful and indispensable a friend to fall by the wayside without making an effort at rescue. He knows that the happiness of himself and his fellows depends on medicine more than all the professions, learned and unlearned, put together. So that it is to be hoped he will look carefully into the grievances of the medical practitioner, and see if nothing can be done to control the hospitals and the horde of quacks and of other competitors who take the bread out of his mouth. At the same time medical men must keep their powder dry as well as put their trust in God. They will have to insist upon getting a really representative General Medical Council, as a first step towards advancing Medical Acts for the protection of the public against fraudulent quackery. In Prague medical men have struck against Sunday work, and have agreed not to see any patients between Sunday mid-day and 8 o'clock in the evening. Certain medical men are told off to attend urgent cases, and their names and addresses are duly published. This step is one of obvious prudence on the part of a profession that is subject to the most arduous and exacting toil both by day and by night. Why should not a similar common-sense rule be adopted by medical practitioners in the United Kingdom?

Aberdeen and School Ophthalmia.

For many months past an epidemic of epidemic conjunctivitis has been raging amongst the school children of Aberdeen. On the 16th November no less than 21 new and 66 old cases were treated at the Aberdeen Eye Institution. Naturally it would be imagined that the school authorities would have taken immediate and stringent steps to stamp out the malady. The surgeon to the Institution, Dr. Galloway, however, has written to the *Aberdeen Journal* a letter that reveals an extraordinary attitude on the part of the School Board, which appears to be absolutely indifferent to the serious issues involved. Since the 1st of January of the present year 1,048 cases have been treated at the Institution, and doubtless many have been under medical men elsewhere. Dr. Galloway states that under his care is a recent case of a child of nine years, whose mother received a note from a headmaster of a board school saying that unless the child were sent to school at once a prosecution would follow. A similar communication reached the parents of a little girl who that very morning arrived at the Institution "with her eyes glued up with discharge." The sooner the School Board of Aberdeen infuses a leaven of common-sense into the administration of affairs the better for its citizens. Surely in face of such an epidemic every public school, if not at once closed, should be submitted to rigorous skilled medical inspection from day to day.

Medical Men and Fees for Medical Attendance.

Of all the honourable customs that dignify and grace the medical profession perhaps the most scrupulously cherished is that which forbids a medical man to accept fees from a brother in his own profession. Indeed, so far is the principle extended that in many cases the children of a medical man are also exempted, even when they are established in other walks of life, and their father has long since been dead. In a recent King's Bench action for damages, however, the plaintiff, a medical practitioner from Kingston, made some extraordinary statements upon this point. He had been injured as the result of a trap accident, and had received a bill from a local doctor, who had attended him, for £24 15s. In answer to a remark from the Judge, counsel for the plaintiff said that it was by no means an uncommon rule now for a medical man attending another medical man to charge for his services. We beg to differ absolutely from the gross perversion of facts conveyed in that assertion. Now and then a well-to-do medical man may press a fee, directly or indirectly, on a less prosperous brother professional, but that there is any general custom of charging fees for such services is untrue. It is not easy to imagine how that curious belief could have suggested itself to learned counsel, unless, indeed, the account was introduced by the solicitors for the sake of swelling the claim for damages. But why, in that case, bolster it up with so mendacious an assertion?

The Proposal for a State Medical Service in Ireland.

THE proposal for a State Medical Service in Ireland put forward by the Viceregal Commissioners on Poor-law Reform, contains a condition to which, on general grounds, we think serious objection should be offered. It is that "the proposed Irish Medical State Service should, at all events for the present, be restricted to candidates educated in Ireland." We doubt whether it would be possible to induce Parliament to grant public money for a Service restricted in such a way, but, apart from this, the proposal itself opens very unpleasant prospects. We have long struggled against the iniquitous system under which certain hospital appointments in England are closed against Irish and Scottish candidates, and such appointments are becoming fewer every year. What is to be thought, then, of the suggestion that the public medical service of a whole country should be limited to candidates from three or

four schools? If a State Service is to be founded for Ireland, it should be as free and open to all comers as the other Government services. The practical difference may be slight, as it is unlikely in any case that many English or Scottish candidates will be attracted. It is, perhaps, somewhat early to discuss the details of the scheme, but the point of principle raised seems to us important.

Mr. Birrell and the Teaching of Hygiene.

The answer given by Mr. Birrell to the deputation which waited on him last week in reference to the teaching of hygiene in primary schools, while courteous and even sympathetic, hardly went as far as one would have hoped. Doubtless some of the members of the deputation were in part responsible for the undecided character of the interview, since they did not content themselves with pressing forward the special objects they had in view, but dragged in altogether extraneous subjects. The special points put forward in the memorandum presented to Mr. Birrell were three—the teaching of hygiene and temperance in the primary schools, the training of teachers in these subjects, and the reporting on them by the Inspectors of Schools. Not content with this fairly suggestive text, one at least of the deputation seized the opportunity to discuss the quite different subject of medical inspection of schools. With regard to the first of the three points raised, Mr. Birrell seemed to think that there would be some difficulty in arriving at any body of doctrine suitable for the instruction of the young, on which men of science would be in agreement. This, however, does not present any formidable obstacle, for though there are differences of detail between individual thinkers, yet the elemental principles of hygiene and temperance receive the assent of all. With regard to the other points, the Minister of Education was a little more encouraging, taking care, however, to emphasise the importance of hurrying slowly.

Herbalism Generously Disposed.

The Privy Council grinds slowly, but in the case of the herbalists' charter, of which we spoke last summer, it has ground exceeding small. In fact, it has had the good sense to grind the idea of a charter out of existence altogether. It was, indeed, hardly conceivable that any responsible body would entertain such a farcical notion for a moment, even though the three recognised colleges in the United States offered free scholarships to students from England who would go to them for "training" for the professoriate. But, nothing dismayed, the herbalists have apparently turned their attention to cancer research, and great deeds are about to come forth. To encourage this beneficent movement, a Mr. W. H. Webb—we are not sure if he is "professor," but perhaps he will pardon our ignorance of his style—is prepared to grant the use of his sanatorium in Lancashire for two years, free of rent and rates, to a committee of enquiry. If their report is favourable, he will hand the sanatorium over to a "Board of Education" to be composed partly of members of the People's League of Medical Freedom, and partly of those of other equally important bodies at half price. This offer seems rather an unpromising way of getting rid of the sanatorium if it is a white elephant, and rather a grotesque one if it does so much good under its present *regime*. Men have been known to give up much for their faith, but a sanatorium at half-price strikes us as unparalleled generosity.

PERSONAL.

The Empress of Germany has signified her gracious consent to be a patroness of the Fourteenth International Congress of Hygiene and Demography, which is to take place in Berlin in September, 1907.

Dr. Colston Wintle was re-elected chairman of the Bristol Health Committee on November 20th.

Dr. F. W. Bennett has been elected secretary of the Section of Geology, and Dr. Allan Warner secretary of the Section of Physiology for the British Association meeting in Leicester next year.

Professor Bernherd Fraenkel, the veteran laryngologist, received a large number of presents and addresses on attaining his seventieth birthday last week. Sir Felix Semon personally took him an illuminated address from the Laryngological Society of London.

Dr. Hebert, on whom a murderous attack was made in France last week, is a Canadian graduate, who, after qualifying in England, settled down in London. Dr. Hebert now lies at the Lariboisière Hospital, shot in the forehead and the jaw.

At the fifth meeting of the Royal Commission on Vivisection, Dr. Thane, Inspector under the Experiments on Animals Act, concluded his evidence.

The prizes to the members of the R.A.M.C. Volunteers at Manchester were given away last Saturday by Sir Alfred Keogh, K.C.B., M.D., Director-General of the Army Medical Service.

On the 23rd inst., the President of the Royal College of Surgeons (Mr. Henry Morris) took the chair at the annual dinner of present and past students of the National Dental Hospital and College, Great Portland Street.

Dr. Horton-Smith Hartley, M.V.O., has been appointed a physician to the Brompton Hospital for Consumption, Dr. Cecil Wall assistant physician, and Dr. Dundas Grant surgeon in charge of the throat department.

Dr. G. Norman Meachen will deliver a lecture on the place of music in the healing art before the Incorporated Guild of Church Musicians, London, in the Brinsmead Concert Hall, 18, Wigmore Street, W., at 3 p.m., on November 29th.

Last week the London Courts were occupied with the re-trial of the notorious Cardiff case, in which two local medical men, Dr. Skrime and Mr. Lynn Thomas, were sued for £2,000 damages for alleged improper treatment of a fractured humerus. The case was adjourned until to-day.

The treasurer of Guy's Hospital has received two anonymous donations, of £200 and £10 respectively, towards the fund for the endowment of medical education and research at Guy's Hospital.

A CLINICAL LECTURE
ON
THE DECHLORIDATION TREATMENT IN CARDIAC AND RENAL DISEASE.

By Professor F. WIDAL, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

A SUBSTANCE indispensable to life, chloride of sodium plays an important part in the organism. The blood and lymph contain a certain fixed proportion which ensures the constancy of the osmotic tension in the tissues and fluids of the body.

In this latitude the average man consumes about half an ounce of salt daily, to which must be added some 200 grains added to his food for cooking purposes. This quantity is greatly in excess of physiological requirements, and most of the salt ingested passes through the organism without having served any useful purpose.

Under normal conditions the ingestion and excretion of the chloride are fairly balanced. Any addition to the quantity taken is followed by an increase in the output until equilibrium is re-established. *Per contra*, when an organism has been deprived of salt and has become impoverished, the first supplies are added to the reserves until these have reached their normal standard.

Variations in the chloridation of the organism entail variations in the hydration of the tissues, as is readily shown by periodical weighing. In the normal subject this variation does not exceed three to four pints, while in respect of the chlorides the variation limit is about five drachms. This equilibrium is so constant that in the healthy an excess of chlorides is not followed by hydration, owing to the prompt excretion of the salt.

Since the ebb and flow of the "organic water" is determined by the chloridation, it is easy to conceive that when the kidney is impermeable much larger quantities of salt may be retained, leading to hydration of the tissues and œdema.

The excess of chloride does not remain in the blood, but passes into the tissues, whither it takes with it a certain proportion of water, and in patients in whom the chlorides are inadequately excreted the excess is found in the œdematous serum (Achard). This fact may be viewed in contrast with the accumulation of urea which takes place in the blood. The administration of salt in certain cases of Bright's disease will suffice to determine œdema, so that it constitutes a dangerous article of diet for them and must be withheld.

The dehydrating action of the dechloridation treatment in the subjects of Bright's disease can be demonstrated with the precision of a laboratory experiment. In one case, for instance, an attack of œdema and albuminuria could at any moment be precipitated by a milk diet, symptoms which as rapidly cleared up when a regimen of bread, potatoes, and red meat was substituted. The explanation is that the 150 grains or so of salt contained in the milk rendered it a pernicious aliment, while the suppression of salt in the meat diet rendered the latter a very wholesome one.

Hydration secondary to chloride retention takes place in two stages. It is already far advanced when its existence is manifested by perceptible œdema. That stage is preceded by a period of progressive hydration not associated with any visible sign. This may reach 10 or 11 pounds. Daily weighings reveal the existence of this pre-œdematous period, and enable us to foretell with considerable accuracy the probable date of the appearance of clinically perceptible œdema; in fact, systematic weighing yields information quite as exact as the chart of urinary chlorides, and shows whether the salt ingested is or is not retained.

Manifest œdema that invades and distends the subcutaneous tissues is the least alarming feature of the hydration process. Vastly more injurious is the invisible œdema revealed by the scales. Permeating the various organs, it may give rise to visceral symptoms with which we are familiar in uræmia, and which are due to chloridæmia, but by this term we mean a state of chloride-retention, and not its actual presence in the blood.

This visceral chloridæmia may be manifested by dyspnœa, vomiting, diarrhœa, headache, Cheyne Stokes' respiration, attacks of eclampsia, according as the incubus falls upon the lungs, the digestive apparatus, or the nerve centres. The powerful and immediate effect of dechloridation proves that these symptoms belong to the state of chloridæmia.

Even albuminuria is often influenced by the richness of a diet in salt. In many cases it will be found to rise and fall in proportion to the amount of salt taken. In this case it is a renal manifestation of the chloridæmia. My view is that there is local œdema of the kidneys, which in some patients increases the albuminuria and intensifies the chloride retention.

The impermeability of the kidneys for chloride of sodium is only comparative; it varies in different individuals, and in the same subject at different periods of the disease. The impermeability may be very pronounced, for in some renal patients the kidneys only excrete a few grains of chloride in the twenty-four hours. The kidneys may be equal to the excretion of this small quantity of chloride, and if this amount be not exceeded in his food there will be no retention, no chloridæmia, no œdema. Give an excess of chloride, and as it cannot be got rid of by the kidneys, it will accumulate in the tissues and cause œdema.

The recognition of the comparative impermeability of the kidney in respect of chloride of sodium explains why a chloride-free diet, in addition to its readily understandable preventive action, exerts such a remarkable curative effect. If in the case of a subject of renal disease who is waterlogged we impose a chloride-free regimen, the infiltrated liquids are driven off by the cardio-vascular impulse, and the reserves of chloride are then reduced by the difference between the quantity of chloride that the kidney can pass and that taken in the food. In other words, there will be a chloride discharge in spite of the comparative impermeability of the kidney, and this will be accompanied by de-hydration and subsidence of the œdema. The milk diet, which conveys more chloride than many renal subjects can eliminate, is therefore less beneficial in such cases than a chloride-free diet, even though it comprises meat.

The dechloridation and dehydration that take place under the influence of a low-chloride diet are often very profuse, and when the process has been set going the chlorides may continue to flow freely from the tissues to the kidneys, and, after all trace of œdema has disappeared, the permeability of the kidneys for the chlor de may remain adequate for many months. In other instances the dechloridation takes place more gradually, and when such is the case the chloride-free diet must be maintained very strictly for a long time under penalty of a gain in weight on the least excess. Some patients are so sensitive that they become œdematous even on a milk diet.

Speaking generally, then, the curves of chloridation and hydration oscillate in the same directions in renal subjects, the richness of the œdema liquid in chloride being about the same as that of the serum, viz., five

or six parts per thousand. Sometimes, however, there is a more or less marked divergence between the degree of hydration and the intensity of the chloride retention, the patient retaining much more salt than water. This is specially seen in the subjects of interstitial nephritis, who are little liable to œdema, yet accumulate chlorides (dry retention). The explanation may be that in this case the chlorides are retained in combination with the albuminoids.

In some cases of Bright's disease there is marked disassociation of the eliminatory functions of the kidney, which, though retaining part of the chlorides, passes normal quantities of phosphates and urea, but we must remember that while urea tends to accumulate in the blood, the chloride on the contrary tends to accumulate in the tissues. This explains how it is that the proportion of chloride in the blood serum varies very little whatever the degree of chloride retention.

The quantity of urea contained in the blood stands in a certain relationship to the amount of albumen ingested, and we are thus enabled to establish an "index of urea retention." When, however, the proportion of urea in the blood attains a high figure, 50 to 60 grains per litre, we may infer the existence of marked retention of urea without enquiring the amount of albumen ingested. These figures, however, can only be reached at the terminal stage of the disease, consequently the quantity of urea present in the blood furnishes an important element of prognosis. Whatever the degree of infiltration and the gravity of the general symptoms, if the proportion of urea in the blood is approximately normal, or at any rate inferior to 15 grains per litre, we are justified in hoping much from dechloridation, whereas if the proportion of urea exceeds 30 grains per litre the prognosis is of the gravest.

It is not claimed for the dechloridation treatment that it can avert all the accidents to which the victims of chronic renal disease are liable, but it enables us to combat and to avert certain formidable complications which *per se* may cause the patient's death. In the subjects of chloride retention there are two distinct indications: one is to rid the organism of the chloride and water that clog the organism, the second is to draw up a regimen in which the quantity of chloride ingested is proportioned to the permeability of the kidney for the salt.

On commencing the dechloridation treatment of a person suffering from renal disease, we must begin by taking his weight and putting him on a strict chloride-free diet. The loss of weight will enable us to estimate the effects of the treatment on the œdema, visible or not, of the subject.

It is easy enough to establish the total amount of chloride ingested: if the patient is on a milk diet we have only to calculate 1 gramme 60 centigrammes per litre; if he is on a mixed diet without the addition of salt, we may reckon that he is taking 25 grains of natural chloride; while on certain restricted diets the quantity may fall to 15 grains daily.

The loss of weight may take place in some instances from the very commencement of the treatment, and that indicates a comparatively satisfactory degree of permeability; or the dechloridation may only take place slowly, the weight remaining stationary for some days, the grand discharge being delayed for a time. The chloride discharge takes place more slowly in patients who get up part of the day than in those who remain in bed.

The process of dechloridation may come to a stop, and some œdema remain which cannot be got rid of. In that event we must call diuretics to our aid. It is particularly apt to fall short in persons in whom the œdema is of long standing.

When dehydration is complete (*i.e.*, when the weight continues to fall after the disappearance of all trace of œdema) and the weight remains stationary for several days following, we may then try within what measure it is safe to give salt, proceeding, however, with the greatest prudence. We may begin by adding 40 or 50 grains of salt daily to his food; if the salt is duly eliminated and there is no increase of weight we may gradually raise the dose to 80, and by-and-bye to 160 grains, by which time the kidney may have recovered a comparatively free permeability for chloride, but it behoves us to remain rather below the limit of permeability.

The drugs usually associated with the dechloridation treatment are theobromine and its derivatives. Squills and nitre have only a trifling effect on renal patients, acetate of potash is rather more active, but its effects are uncertain. Theobromine, then, is the drug to be preferred, but it is unnecessary so long as diuresis takes place under the sole influence of the dechloridation, and it is unwise to seek to rid a renal subject of more than three pints of his hydration water in the twenty-four hours. In any event, the use of theobromine will not dispense with the necessity for a chloride-free diet.

The chloride-free regimen allows us to provide the patient with a dietary to his taste without losing sight of the object we have in view. Ordinary bread contains between 60 and 120 grains of salt to the pound. Saltless bread, which can be made without difficulty, does not contain more than 8 grains to the pound. Meat contains on an average 8 grains to the pound. It may be taken raw, grilled, or roasted, without salt, but with as much butter as desired. Red meats are in no wise injurious. Fresh water, fish, eggs, fresh butter and cream may be given. Vegetables, especially potatoes, rice and salads, also enter into the scheme. By using certain condiments we can effectually mask the absence of salt. Sweetmeats, pastry, fruits and jams are permissible, and chocolate is the more beneficial in that it contains theobromine. We must not authorise more than four pints of liquid in the twenty-four hours. Tea, coffee, beer, and even wine may be allowed, if taken in moderation.

The properties of milk in the treatment of certain forms of nephritis have long been known, and it owes its effects no doubt in great measure to its poorness in salt—in fact we have been carrying out the dechloridation treatment without knowing it. We must not forget that milk is a food which may, under certain conditions, suffice to maintain the nutrition of a patient for a time. But if we give milk to the subjects of Bright's disease regardless of quantity we may be giving a diet far too rich in chloride, and in any case too rich in albumen and water for many of them. The quantity of milk required to maintain nutrition contains close upon four times more chloride than a mixed diet fulfilling the same purpose. It contains three quarts of water and at least four ounces of albumen, that is to say, far more than the mixed diet.

The various chloride-free regimens, while enabling us to bring about the elimination of the surplus chloride and to prevent retention, enable us to devise dietaric to suit the requirements and tastes of the patient without infringing the rules that direct the choice of food for the subjects of renal disease.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by T. Gillman Moorhead, M.D., F.R.C.P., Physician to the City of Dublin Hospital, on "Post-Traumatic Neuroses."*

THE Spanish Minister of the Interior has laid before the Senate a Bill providing for the regulation of the labour of women and children, and for the creation of a national institute of social thrift.

AT a meeting of the Medico-Psychological Association of Great Britain and Ireland on November 15th, Dr. Robert Jones, of Claybury Asylum, was presented with an illuminated address in acknowledgment of the services which he has rendered to the Association as Honorary General Secretary and President.

ORIGINAL PAPERS.

ON THE TREATMENT OF DIABETES WITH SECRETIN. (a)

By J. R. CHARLES, M.A., M.D.CANTAB., M.R.C.P.,
Assistant Physician to the Bristol Royal Infirmary.

BAYLISS and Starling have demonstrated that when hydrochloric acid comes into contact with the epithelial cells of the duodenum and upper part of the jejunum, a substance is found therein to which they gave the name secretin. This substance is carried by the blood stream to the pancreas, on the external secretion of which gland it acts as a specific stimulant. The secretin is only formed in health, when free hydrochloric acid is passing along the duodenum, which only occurs in the presence of food.

The idea has been promulgated that it is possible, since secretin acts as a specific stimulus to the visible external secretion of the pancreas, that it may also act as a similar stimulus to the assumed internal secretion. By many it has been supposed that the internal secretion is formed in the cell-islets of Langerhans, but this appears to be by no means certain. It has been shown by Dale, who believes that these islets are derived from the ordinary alveolar cells, that there is every transitional stage between the alveolar cells and the islets. Moreover, he has shown that the proportion of islet tissue can be much increased by prolonged stimulation of the gland by secretin, and he regards the islets as cells in a state of exhaustion. If, therefore, there is only one type of secreting cell in the pancreas to elaborate both the external and internal secretions, it would appear to be not unreasonable to presume that both secretions might be stimulated by the same excitant.

A paper on the treatment of diabetes by acid extract of duodenal mucous membrane was recently published in the *Biochemical Journal* by Moore, Edie, and Abram. As these authors point out, even if it be granted that the duodenum yields a chemical excitant for the internal secretion of the pancreas, and that in the absence of this internal secretion glycosuria occurs, then there are three places at which a breakdown may occur, resulting in diabetes. Firstly, at the duodenum, on account of the non-secretion of the excitant; secondly, at the pancreas; thirdly, in the oxidising tissues, such as the liver and muscles. Perhaps also it might be added that in some cases a defective supply of hydrochloric acid might be the cause of the failure of the elaboration of the secretin.

It must not, therefore, be supposed that all cases of diabetes will be benefited by the administration of secretin. In the paper above referred to five cases treated with secretin are mentioned. In two the results were negative, but it is stated that the periods of observation were short and the doses insufficient. In the third case, a man, æt. 25, after administration of the extract for some weeks the sugar fell in amount and gradually disappeared entirely. The patient increased in weight and the polyuria disappeared. Unfortunately, a few months later, after leaving the infirmary and giving up his extract, he developed phthisis, the sugar reappeared, and he shortly afterwards died. Another case was that of a boy, æt. 7, in whom the sugar excretion gradually fell, until after five and a half weeks' treatment it was entirely absent, and remained so, even after the treatment had been suspended. In a further case, a girl, æt. 9, the sugar entirely disappeared after three weeks' treatment.

During the last few months I have treated three patients by this method, but unfortunately with entirely negative results. The cases, even though failures, are, however, I think, worth recording. At present it is quite uncertain what type of patient suffering from the disease is likely to respond to the treatment, yet if both negative and positive cases be recorded, some facts may be brought to light which may make this point more clear.

NOTE.—Neither acetone nor diacetic acid were present in this case.

Case III.—John W., aged 53, shopkeeper. Ad-

mitted November 16th, 1905, and discharged January 16th, 1906. Complained of thirst, excessive appetite, polyuria, dryness of skin, and loss of weight of three and a half years' duration. This man was treated by diet, codeia and aspirin. He went out unrelieved. A quantitative and qualitative investigation of his urine was made twice a week. The analyses remained remarkably constant. Acetonuria was present throughout. Comparing the last with the first analysis, we have :—

Date.	Oz.	Sugar.	Urea.	Acetone.	Diacetic Acid.	Weight.
						st. lb.
Nov 20	84	2,499	882	Present.	Absent.	8 10
Jan. 15	104	2,631	676	Present.	Present.	9 0½

Since his discharge he has been kept under constant observation, and on February 6th secretin treatment was commenced. As the daily amount of urine was only roughly estimated, the amount of sugar was calculated by grains per ounce. The following figures show that little improvement took place. Acetone disappeared on May 15th, but rapidly returned :—

Date.	Grains per oz.	Date.	Grains per oz.
Feb. 13	28.3	April 20	Began "Antiglucosine."
,, 27	28.9	May 8	26.2
Mar. 3	26.8	,, 15	29.2
,, 9	28.6	,, 21	21.4
,, 16	31.4	June 11	39.2
,, 23	25.7	,, 21	Stopped "Antiglucosine."
,, 30	32.2		

The "antiglucosine" mentioned above is an acid extract of duodenal mucous membrane, and differs from the solution of secretin first used in being made freshly every other day. Solutions of secretin are known to become inert on keeping, and it was thought that the negative results obtained with the first solution of secretin might be due to the fact that it had been kept too long, and hence "antiglucosine" was substituted. The treatment has for the present been discontinued, as it was found that the solution was liable to undergo decomposition on very hot days.

The most satisfactory results obtained by Moore, Edie, and Abram were in two children, whereas these patients were all adults. The diet while the observations were being made was, of course, kept constant.

APPENDICO-ENTEROSTOMY.

By SETON PRINGLE, M.B. (Univ. Dub.), F.R.C.S.I.,

Surgeon to Mercer's Hospital, Dublin.

SOME years ago it was the fashion to unhesitatingly condemn the vermiform appendix as a useless and dangerous organ which it was the duty of every surgeon to remove on the slightest provocation. However, more recently we have come to recognise that it is not an organ of merely developmental significance, and that not only has it its part to play in the normal processes of the body, but also that it may be used by the surgeon in several ways in treating diseased or abnormal conditions of the intestines. Sir William Macewen (*a*) in his Huxley Lecture for 1904, made a systematic effort in its defence when he showed that at least it had a possible function "of value in digestion." Before this date the operation of appendicostomy, which now holds a recognised position in surgery, had been advocated by Keetley (*b*), and had been performed several times. Although this operation gives an easy and safe method of applying lavage to the great intestine, the difficulty of passing a tube up through the ileo-cæcal valve, and thus enabling us to also treat the lower ileum, was recognised. However, quite recently Ewart (*c*) has described in detail a method by which this may be accomplished. No doubt this is quite a feasible procedure in skilled hands in the majority of cases, but I think it will never be without an element of risk in ulcerated conditions of the gut, as a stiff instrument is required, and an element of doubt exists as to when the valve has been successfully passed, since the only *positive* indications of this fact are the actual palpation of the catheter through the abdominal wall, and the obtaining a skiagram of the instrument with a stillette in position. Recognising the limitations of appendicostomy, I have in the case about to be reported employed a procedure which has as far as I know not yet been described, and which adds another to the possible uses of the appendix. The operation briefly consists in implanting the opened tip of the appendix into the lower ileum, bringing out and fixing the middle third of the organ to the skin, then, after the wound in the parietes has healed, this loop can be opened, leaving both the lower end of the small and the whole of the great intestine easily accessible for lavage.

History.—C. J., unmarried, female, æt. 22, admitted to Mercer's Hospital, May 14th, 1906. Three years ago she had both her ovaries removed by a gynæcologist for double tuberculous pyosalpinx, the wound, however, suppurated, and a ventral hernia developed, while she continued to complain of considerable pain in both iliac fossæ. In April, 1905, when she came under my care, I operated for the cure of the hernia, and then found great matting together of the intestines in the pelvis, and on endeavouring to separate these adhesions I came on unmistakable evidence of tuberculosis. A few weeks after her discharge from hospital with the hernia cured, the pain in the iliac regions increased in severity and diarrhœa set in. From this time till last May, when I readmitted her, the diarrhœa continued, the stools numbering six to twelve per diem, fluid in character, containing mucus and occasionally blood, while she also complained of constant abdominal pain with frequent attacks of greater severity, especially referred to the right iliac fossa. For several months before readmission, she was treated in the extern department by Wright's vaccine method, and although her tuberculo-opsonic index was raised from ·65 to above normal, no appreciable improvement had taken place.

Condition on Admission.—On examining the abdomen, the only sign of importance which could be made out was tenderness along the entire course of the colon, but most marked in the right iliac fossa, where a sense of indefinite fulness was conveyed to the palpating hand.

Operation.—As we were here evidently dealing with a case of chronic tuberculosis of the intestine, I determined to perform the operation briefly

(*a*) "Brit. Med. Journ.," 1904, Vol. I., p. 873.

(*b*) "Brit. Med. Journ.," 1894, Vol. II., p. 1,112.
(*c*) "Lancet," May 12, 1904.

outlined above. In detail the technique was as follows: The abdominal cavity was opened by McBurney's muscle-splitting incision, but placed an inch or so nearer the middle line, the appendix was easily found lying to the inner side of the cæcum with the top adherent to the root of the mesentery of the lower ileum. When this adhesion had been freed, the ileum about four inches above the ileo-cæcal valve was pulled into the wound and caught in a Doyen's stomach clamp, so that its unattached border presented in the concavity of the forceps. The peritoneal cavity was then packed off with gauze, leaving only the appendix and the portion of ileum included in the clamp exposed. The next step consisted in passing a silk suture through the sero-muscular coats of the appendix about a quarter of an inch from its tip, and after making a small incision into the centre of the clamped part of the ileum, each end of this fixation suture was carried on a needle through the wall of the gut from within out, so that on tightening it the tip of the appendix would be pulled into the incision in the ileum, and fixed there (Fig. 1). My assistant then took charge of

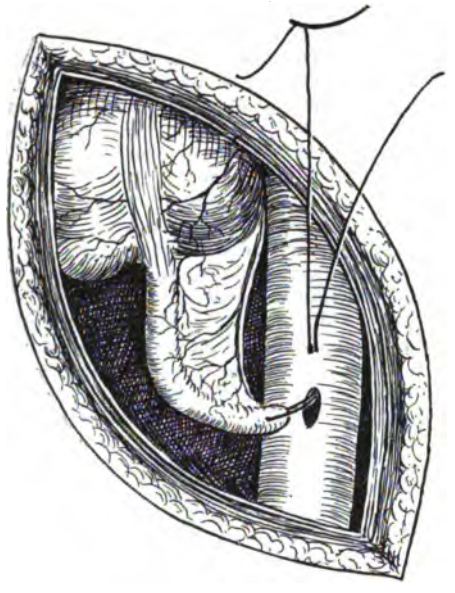

FIG. I.
Showing incision in ileum and fixation suture in position, immediately preparatory to cutting off top of appendix and tightening the suture. The clamp on the ileum and the gauze packing are not shown.

the two ends of the suture, and I, after cutting off and removing the tip of the appendix immediately insinuated its open end into the lumen of the ileum, while he tightened and tied the suture, thus fixing the opened appendix into the small gut. The line of junction was next rendered secure by two rows of continuous silk suture and the knot of the fixation suture on the peritoneal surface of the ileum buried by a few points of fine silk (Fig. II.). The clamp and protective gauze pads were then removed, and the operation area sponged with salt solution. The preceding and following steps of the operation will be more clearly understood by a reference to the accompanying semi-diagrammatic sketches. As a precautionary measure, and also to relieve tension, I fixed the ileum on either side of the anastomosis to the deep surface of the parietal peritoneum by a few stitches, and then closed either end of the incision in the peritoneum, leaving about the middle third of the appendix presenting in the depth of the wound in

the parietes and fixed there by the last loop of either continuous suture in the peritoneum, and also by a mattress suture through either flap of peritoneum, and the mesentery of the organ, which latter I tied loosely so as not to strangulate the circulation (Fig. III.). The muscles and

Peritoneum closed, loop of appendix presenting and fixed mattress suture through the mesentery tied, points of suture fixing ileum in neighbourhood of anastomosis to the parietal peritoneum.

aponeurosis were then approximated by interrupted catgut sutures and finally the two ends of the skin incision closed, while the appendix was fixed on a level with the skin in the centre of the wound by four silkworm-gut stitches.

Progress of the Case.—The wound was not dressed for eight days, and was found soundly healed except for a gap in the centre, from which the loop of appendix had retracted as the stitches fixing it to the skin had lost their hold on the wall of the organ. It necessitated administering an anæsthetic to find the loop which lay at the bottom of the wound in the muscles, it was then opened by a transverse incision dividing three-fourths of its circumference, and the cut edges stitched to the skin. Since then it has been quite easy to see the two openings and to pass two No. 8 soft catheters, one into the cæcum and another into the ileum. I now daily wash out the intestines with antiseptics; the first solution I tried was a 1 per cent. silver nitrate, but as this caused intense pain it was discontinued and protargol used instead. There has never been any discharge of fæcal matter from either opening. It is yet too early to form an opinion as to the final result of the treatment.

If I am again called on to do this operation I intend to make several slight alterations in technique. It would, I think, be advisable to fix the free end of the cæcum as well as the ileum to the parietal peritoneum, as with a short appendix the tendency to retraction is marked, and also to pass a guiding suture, leaving the ends long, through the summit of the loop of appendix, so that in case of retraction the organ could easily be pulled up into the wound. If thought desirable it would, I consider, be quite sufficient to crush the tip of the appendix before insertion into the ileum, and so obviate the opening of an organ which is a favourite haunt of bacteria. With these additions I venture to hope that the procedure above described will be of value in a few selected cases, but I fear its performance takes too long to permit of its being justifiable in a weak subject—for instance, in a patient suffering from typhoid fever.

Postscriptum.—The above account of the case was written in June last, but, unfortunately, the hospital was closed down in July to allow the drainage to be overhauled, and at the same time I left town for six weeks. On resuming work I found that both the openings had closed, and consequently the treatment could not be recommenced. I therefore regret that no definite conclusion can be arrived at, although the patient appears better and the diarrhœa is limited to three or four motions per diem.

OPERATING THEATRES.

NORTH-WEST LONDON HOSPITAL.

EPITHELIOMA OF THE FLOOR OF THE MOUTH.—Mr. MAYO COLLIER operated on a case, a man, æt. 54, which proved to be one of considerable interest from the fact that he adopted a procedure formulated and published by him some 25 years ago, which he thought for simplicity, thoroughness, and freedom from danger, both during the operation and in the after treatment, leaves little to be desired. Mr. Collier said that here he was confronted with a state of things in which one of two courses only could be followed. No half measures were permissible In this case the floor of the mouth was extensively involved by a new growth about which there could only be one opinion. It was not syphilis; there was no history of syphilis; and the amount of new growth as compared with the ulceration was disproportionate. It was hard; the sublingual glands were involved; and it had already invaded the tongue in the neighbourhood of the frænum. The growth had started as a small ulcer on the frænum linguæ, and had gradually, within the last six months, attained its present dimensions. There were enlarged glands to be felt in both sub-maxillary triangles The patient was not suffering much pain or inconvenience, but the presence of the growth was evidently telling on his strength. No question of the growth being tuberculous could be entertained. No organic disease could be detected in the thoracic or abdominal organs. Mr. Collier said that under these circumstances, if the whole growth could be got well away, and if the whole of the glands and cellular tissue in the submaxillary triangles, and in the neighbourhood of the mylo-hyoid and geniohyoid muscles could be explored and removed, a good prospect of prolonging the patient's life in fair comfort and usefulness existed. He quoted two cases in which he had performed a similar operation to the one he was about to do, seven and five years ago respectively. One of the patients had now lived for seven years in comparative health, whilst the second had died only quite recently from pneumonia following influenza. In neither case did the disease reappear. These, as well as other cases, were, he thought, very encouraging, and made one look forward to and hope for the time when, if a thoroughly efficient and complete operation was the rule in these cases, many more lives would be prolonged than was the present experience. An incision was made on each side from the tip of the mastoid process, curving downwards to the centre of the great cornu of the hyoid bone and upwards to the prominence of the lower jaw one inch external to its centre. After dividing the skin, superficial fascia, and platysma, the deep fascia covering the submaxillary gland was incised throughout the entire length of the skin incision. The submaxillary gland was next removed in its entirety, not forgetting its deep portion extending to the floor of the mouth as well as that part which is tucked in between the mylo-hyoid and the genio-hyo-glossus. The facial artery and vein were next ligatured in two places below and above the gland. Any gland or cellular tissue existing in this space was carefully removed to the last speck. The lingual artery was now found by a little blunt dissection and tied, the site of the ligation and the empty space being lightly packed with dry ribbon cyanide gauze. The next step was to incise the mylo-hyoid muscle on each side transversely near the prominence of the chin up to and as far as the outer border of the genio-hyoid. This being done, the skin surface of the mylo-hyoid was carefully examined by insinuating the index finger one each side between the skin and the muscle, and removing the smallest glands that could be detected. A similar search was made between the mylo-hyoid and the under-surface of the genio-hyoid. The fingers were next insinuated between the upper surface of the genio-hyoid and the genio-hyo-glossus, and any glands here detected were removed. The next step in the operation was to free the genio-hyoid from the genio-hyo-glossus completely from the hyoid bone to the genial tubercle, so that the finger was quite free to pass from front to back. A little manipulation now freed the whole floor of the mouth from its infra-maxillary attachment. Up to this point the mouth had been entirely at the disposal of the anæsthetist, and

no anxiety had been entertained as to blood finding its way into the mouth and larynx. The mouth was now opened, and a Smith's gag placed as far back as possible and given in charge of a trustworthy assistant, whose duty was to see that the gag did not invade the cavity of the mouth and did not slip at a critical moment, and, whilst doing this, to concentrate his attention on the gag and not on the operation. A stout double ligature having been placed transversely through the root of the tongue one inch from the epiglottis, Mr. Collier, guiding his blunt-pointed curved scissors with his left index finger below, cut through the mucous membrane of the mouth as well as the genial attachment of the genio-hyo-glossus in the mid-line behind the previously removed incisor teeth. With the index finger as a guide, the scissors were made to detach the mucous membrane from the lower jaw as far as the angle on both sides. The tongue, floor of the mouth, as well as the entire growth, were now quite free, and were only held attached to the hyoid bone and the glosso-epiglottic folds. With the linguals ligatured, the tongue and floor of the mouth were now, with complete confidence, drawn well forward and cut away close up to the epiglottis with a pair of curved scissors without the loss of a single drachm of blood. A temporary stout thread, Mr. Collier said, may be placed transversely through the stump previous to this division, but this step was only needful as a precaution in case of bleeding from the stump, which is extremely rare. All oozing being arrested by packing ribbon cyanide gauze into the hollow thus left, two drainage tubes one and a half inches in length were joined together by an intervening double strand of thick silk one inch in width. The silk juncture was placed over the genio-hyoid muscle, and the two tubes were brought out of the inner angle of the wound below in the cleft made in the mylo-hyoid muscle. The gauze packing was then removed, and the skin incision carefully adjusted with fine silkworm gut and horsehair. The wound was dressed with layers of cyanide gauze, and a piece of protective mackintosh was placed over the dressing, so that the two draining tubes should pass through it—being accurately adjusted so that no drainage should soil the upper dressing. Further dressing and bandages having been applied, the patient was removed to bed, instructions being given that he be kept continuously in a semi-prone position. With this precaution Mr. Collier said there would be no tendency for the stump to fall backwards; there would be natural drainage of the wounds by gravity; the mouth could be washed out every hour without risk of overflow into the larynx or œsophagus, and the patient can expectorate and feed with greater ease. Mr. Collier pointed out that there had not been the slightest hitch or difficulty throughout the whole procedure. The linguals were found in less than five minutes. There was practically no bleeding, and the patient left the table in one hour and fifteen minutes from the commencement of the operation, little the worse, as far as his pulse indicated, for his severe ordeal. Mr. Collier said the operation was simple and deliberate, and was capable of doing all that was desired, namely, removing the entire growth with all visible glands. The secret of the success was to retain the patient in the semi-recumbent position, and to wash the sloughing cavity (left by the removal of the floor of the mouth) out at first every hour with a lotion of permanganate of potassium, half a grain to the ounce.

The tubes were removed 48 hours after the operation. The man was then feeling well and comfortable. The wound in the skin had healed by first intention, the pulse was good, and the temperature normal.

It is satisfactory to state that the subsequent progress has been uninterrupted, and the man is now, some days after the operation, practically well.

CHELSEA HOSPITAL FOR WOMEN.

ABDOMINAL MYOMECTOMY AFTER CONFINEMENT.—Dr. ARTHUR GILES operated on a woman, æt. 37, a patient of Dr. Carson Smyth's. Her history was that four years previously she had been the subject of an extra-uterine pregnancy in the left tube. Intra-peritoneal rupture occurred, and Dr. Giles operated upon her at the Tottenham Hospital. Her first pregnancy after the operation began about ten months ago. During its course, Dr. Smyth discovered a tumour in the upper part of the uterus; he considered that labour would not be interfered with, and his anticipation proved correct. Six weeks after the confinement he sent her to the Chelsea Hospital for Women. On examination, a firm tumour, the size of two fists, was found connected with the uterine fundus. When the abdomen was opened the tumour proved to be a large pedunculated fibroid. Myomectomy was done by cutting through the peritoneum round the pedicle, shelling out the tumour, and securing the stump with ligatures applied by transfixion. The abdomen was closed by the usual three-layer method. On cutting across the tumour it was found to be a soft reddish fibroid in a state of necrobiosis. Dr. Giles remarked that there were three points of interest about this case. In the first place, it justified the policy of leaving the non-gravid tube when operating for extra-uterine pregnancy. At the recent meeting in Toronto some of the speakers took up the position that both tubes should always be removed because of the risk of second extra-uterine pregnancy, but the risk of a subsequent pregnancy occurring in the other tube was not, he thought, great enough to warrant its removal in every case. The second point of interest was the fact that, as the abdomen had been opened before, some estimate could be formed of the maximum time that this fibroid had taken to grow. Although it was of considerable size it had been growing for certainly less than four years. In the third place the case had a bearing on the question of the removal of fibroids during pregnancy; he thought it might be taken as a general rule that fibroids connected with the upper portion of the uterus might be safely left until after confinement, unless any acute symptoms supervened, but when the fibroid was attached to the lower part of the uterus it might require to be dealt with during pregnancy in order to minimise danger during labour. With regard to the operation itself, the tumour, he pointed out, was a very suitable one to be dealt with by myomectomy because it was solitary and pedunculated and the uterus had given quite recent evidence of capacity for pregnancy.

The patient made an uninterrupted recovery.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

MEETING HELD NOVEMBER 23RD, 1906.

The President, Mr. CLUTTON, in the chair.

Dr. HALE WHITE proposed and Dr. Frederick Taylor seconded a resolution to the effect that the Council's advice to the Society to join the proposed Union of Medical Societies be adopted. It was carried *nem. con.*

DR. WALTER CARR read a paper—

A CASE OF HÆMORRHAGE INTO THE PREFRONTAL LOBES OF THE BRAIN.

A man, æt. 53, was admitted to the Royal Free Hospital in a semi-comatose condition, having suddenly become unconscious about seven hours before. The pulse was 56 and of very high tension; the urine boiled almost solid with albumen and contained a considerable quantity of sugar, but did not give the reactions for diacetic acid and acetone. Otherwise the results of physical examination were quite negative; there was not the slightest indication of hemiplegia or of any unilateral symptoms whatever. The man gradually improved, and after two or three days completely recovered consciousness; about the seventh day, however, he again became drowsy, his temperature slowly rose, and he died comatose on the ninth day from the onset. After the first day or two the sugar completely disappeared from the urine, and only an occasional trace of albumen was present.

At the *post-mortem* it was found that a small saccular aneurism on the anterior communicating artery had ruptured into the left prefrontal lobe, and that the hæmorrhage had subsequently extended (probably only shortly before death) into the right prefrontal lobe. The kidneys showed an early stage of chronic interstitial nephritis. In this case, despite the presence of sugar in the urine, the patient's aspect was not that of diabetic coma, but uræmic coma seemed at first very probable. The suddenness of the onset was in favour of apoplexy, but in the absence of any indication of a unilateral cerebral lesion this scarcely seemed a justifiable diagnosis.

Dr. A. E. GARROD recalled making a *post-mortem* examination on a similar case. The patient, a man, recovered completely from the affection, but died of a second hæmorrhage.

Dr. JOHN FAWCETT read a paper on a case of

ACUTE PERITONITIS WITH FAT NECROSIS: NO DISEASE OF THE PANCREAS.

The patient, a female, æt. 59, was admitted into Guy's Hospital under Dr. Hale White, for severe abdominal pain and vomiting, which symptoms had come on suddenly on the previous day. The abdomen was not distended nor rigid, but was extremely tender on palpation in the upper part. Laparotomy was performed later, but no pathological changes were found except areas of fat necrosis in the great omentum, and a small amount of extravasated blood. The patient died the following day.

Autopsy.—A recent general acute peritonitis was present. A widely spread fat necrosis existed, and there was a recent small hæmorrhage in the lesser omentum.

The pancreas was firm; no abnormal changes visible in it, even under the microscope. Cultivations made from the spleen and from the blood in the right side of the heart gave a pure growth of the bac. coli comm.

Remarks.—Although most cases of fat necrosis are associated with disease of the pancreas, yet there are a number on record in which no lesion of the pancreas has been found. In the Guy's Hospital *post-mortem* records there were three such cases during the past six years, but in no one of these was a microscopical examination made. In these three cases the condition was as follows:—

Case I.—Woman, æt. 33. Admitted for acute abdominal pain. Laparotomy performed twelve hours from onset of symptoms; nothing found.

Autopsy.—Numerous areas of fat necrosis in omentum and appendices epiploicæ.

Case II.—Woman, æt. 45. Sarcoma of cervical glands: general sarcomatosis. Died of hæmatemesis.

Autopsy.—A healed duodenal ulcer 3 cm. below pylorus, firmly attached to pancreas. Many areas of fat necrosis over visceral peritoneum, especially in neighbourhood of pancreas.

Case III.—Man, æt. 43. Admitted with a perforated gastric ulcer; laparotomy performed and ulcer sutured. Death took place the following day.

Autopsy.—A recent acute peritonitis, and, in the fat of the great omentum, necrotic fat areas.

If the statement be accepted that fat necrosis is always a consequence of pancreatic disease, then such a case as the one here recorded is exceedingly difficult to explain. It may be that an obstruction to the duct or an interference with the blood supply in some cases will result in a freeing of the fat ferment. However, under present conditions of knowledge the pancreatic fat ferment cannot be said satisfactorily to explain either the case related, or those in which there is a necrosis of the pericardial or subcutaneous fat.

Mr. CLUTTON referred to the complexity of the problem, and instanced the cases of slight injury, in which laparotomy shewed extensive necrosis, and which recovered.

Dr. HALE WHITE said that it would be a valuable step if we could diagnose such cases and so prevent a needless operation. In the present case the reason why he had not called in a surgeon sooner was that forty-eight hours after the onset of symptoms the pulse was 90, and there was no rigidity or distension of the abdomen. He commented on the occurrence of severe pain at the onset.

Dr. CECIL BOSANQUET suggested that even when the pancreas was found to be normal it might be the source of the mischief by means of a small hæmorrhage at its border. In support of this was the fact that in many cases in which fat necrosis and hæmorrhagic pancreatitis coexisted the lesion was primarily a hæmorrhage and not an inflammation, and also the fact that so many of the cases such as that of Dr. Fawcett's showed the presence of blood in the peritoneum.

Mr. W. G. FEDDON narrated a similar case in which he had performed laparotomy. A brown fluid was found in the abdomen. The patient recovered.

Dr. H. S. FRENCH and Mr. W. G. SPENCER also discussed the paper.

Dr. FAWCETT replied, and especially referred to Mr. Spencer's suggestion that accessory lobules of the pancreas might be present in these cases, the main part of the pancreas being healthy.

Mr. W. G. SPENCER described a case of

CYSTIC DILATATION OF THE LOWER END OF THE URETER

containing calculi which became engaged intermittently in the urethra. The patient, a young man, had for six years suffered intermittently from difficult micturition and nocturnal incontinence. Generally he presented no symptoms whatever, and the usual evidences of renal and bladder calculus were absent. No abnormal physical signs were noted until he was examined bimanually under an anæsthetic, when a hard mass was found slipping about within the bladder. On the patient straining, this became engaged in the urethra like an impacted calculus. By perineal section a cyst containing three calculi was found tightly grasped in the sphincters. The pedicle of the cyst was traced up to a portion of the orifice of the left ureter, where the pedicle was burnt off. The man had now no urinary trouble.

Mr. CLUTTON read the notes of a similar case that had occurred in a man of twenty. Sudden anuria and pain in the right side were the symptoms. There had been no previous history of stone. After suprapubic cystotomy the patient got quite well.

Mr. MAKINS had seen a similar case successfully operated on many years before, Lateral lithotomy was done.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

President: J. M. REDMOND, Pres. R.C.P.I. Sectional Secretary: F. C. PURSER, M.D.

MEETING HELD FRIDAY, NOVEMBER 9TH, 1906.

The PRESIDENT in the Chair.

SO-CALLED FUNCTIONAL CARDIAC MURMURS.

DR. TRAVERS SMITH read a paper on the above, dealing especially with the pulmonary systolic functional

murmur, or the common "hæmic" murmur. He reviewed the current theories to explain this murmur, and showed how they could all be refuted on ætiological, clinical, or autopsical evidence. It was urged that this murmur had been too closely associated with anæmia; in fact, it had been generally explained on an anæmic basis. The author laid stress upon the facts that, even apart from anæmia, the murmur was common in neurotic individuals, in those who were "out of training," in connection with many fevers (especially during convalescence), in all of which conditions one might expect a "flabby" state of the body musculature and lowering of tone. In most of his cases the author had established a history of some strain, often inconsiderable to any normal individual. Under these conditions the ventricles of the heart were liable to suffer, especially at the weakest point of their outer boundary wall—namely, the infundibulum, or conus arteriosus. The weak myocardium being strained resulted in incomplete systole or actual dilatation of the infundibulum, the blood being forced from the body of the right ventricle at systole through the unobliterated cavity of the infundibulum into the pulmonary artery. This, Dr. Travers Smith submitted, was the cause of the murmur. In proof of this view he urged the following points:—(1) The murmur disappears with rest in bed, recurs if patient allowed up too soon; (2) it is best heard at the junction of the infundibulum and pulmonary artery; (3) it can be traced better downwards over the infundibulum which comes to the surface than upwards over the pulmonary artery which slopes posteriorly; (4) the murmur is heard best in expiration, because the pressure in the pulmonary artery is thereby raised with further strain on the infundibulum. The murmur can sometimes be actually produced by a prolonged expiratory phase; (5) a slight, sudden exertion, as sitting up, diminishes the murmur, as it affords a stimulus to the infundibulum to contract more energetically. Occasionally the murmur increases on sitting up, showing greater weakness of the infundibulum; (6) the murmur is commoner in youth owing to the relatively high pressure in the right ventricle as judged by the loud pulmonary second sound in youth; (7) the murmur disappears with gross dilatation of the right ventricle when the dilatation of the infundibulum fuses with that of the body of the ventricle—in fact it is not heard with a tricuspid regurgitant murmur; (8) when a functional pulmonary diastolic murmur occurs with a systolic one (the author had met two examples) it is best explained upon the hypothesis that blood remaining in the infundibulum regurgitates thence into the body of the ventricle at its commencing diastole; (9) almost invariably the area of superficial cardiac dulness is increased upwards in the presence of a pulmonary functional systolic murmur. Dr. Travers Smith urged that this view afforded the most rational explanation of the ætiology and clinical signs of the murmur.

Dr. MOORHEAD said he regretted that Dr. Smith had not given them his views on the other functional murmurs. He had himself first accepted, without much thought, the idea that the functional murmurs generally were produced by some alteration in the normal relation between the blood and the vessel wall, accepting that normal blood flows through normal vessels without producing murmurs. Very soon, however, he had to give up that idea, and he found it necessary to find some theory which would explain the murmurs heard in cases of acute endocarditis as well as the ordinary so-called functional murmurs. In such cases he could not conceive that the small vegetations that are seen on the edges of the valves were capable of preventing the valves from closing. He then took the view that functional murmurs and the murmur of acute endocarditis were due to muscular relaxation, and were functional in the sense that the muscle from its weakness relaxed, and regurgitation took place. Anything in the way of relaxation that would give rise to aortic systolic murmur—a rare condition, he admitted—would surely also give rise to a pulmonary functional murmur and to a mitral functional murmur. Although it was possible that Dr. Smith's theory would be applicable to the other valves, he was not prepared to accept it fully.

Dr. SMITH, in reply, said that Dr. Moorhead's mental phases in trying to find an explanation for functional murmurs were the same as his own. It was his intention to deal with the other murmurs in another paper. He did not think that Dr. Moorhead's suggestion, that pulmonary and mitral functional murmur ought to be present when an aortic murmur was present, was against his (Dr. Smith's) own view. The exact spot at which a murmur was heard did not indicate the seat of the murmur. He suggested that aortic systolic functional murmur, which was of extreme rarity, was to be explained by the pulmonary murmur, which was the commonest, and could be induced.

SPLENO-MEGALY WITH EOSINOPHILIA.

Dr. PARSONS read a paper on the above subject, illustrating it by a case which he showed. He described the condition of the blood and the patient's general symptoms, and gave details of the history. He said treatment by X-rays had had no appreciable effect.

Dr. ROWLETTE said he had seen the case some years previously, and the spleen did not appear to have increased in size. During observation the health of the patient had remained exceedingly good, apart from the discomfort through the weight and size of the tumour.

Dr. PEACOCKE quoted a case which turned out a case of Hodgkins' disease. The splenic tumour was simply a mass of lymphoid tissue. An operation was successfully performed, and he suggested the removal of the spleen in the case before them as a curative method.

Dr. HARVEY said he had seen cases of an ordinary type treated with X-rays with apparently very different results from those in the present cases. Such treatment was likely to have altered the pathology of the spleen considerably. The effect in animals was to destroy the lymphocytes in considerable degree.

Dr. PARSONS, replying to questions from Drs. Moorhead, Kirkpatrick, and Smith, said the patient at no time had syphilis. He did not consider the cases identical merely because they had eosinophilia. The cases were on the same level. There was no deterioration in health, no threatened shortening of life, and no inconvenience except in the weight of the tumours. Lymphocytosis was not very marked; exactly the same was found in the case of splenectomised animals, which tended to confirm his view that the two patients were functionally splenectomised. Several examinations of the blood had been made before the X-ray treatment was commenced, and there was found to be no diminution in the number of the lymphocytes. Anxious as he was to know the pathology of the spleen, he did not feel justified in recommending its removal, as no inconvenience was caused, and no further enlargement was threatened.

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD FRIDAY, NOVEMBER 16TH, 1906.

DR. TYSON (Folkestone) in the Chair.

A PAPER ON

PSORIASIS IN CHILDHOOD.

was communicated by Dr. James Burnet. The author considers psoriasis may differ in causation in early and adult life, and in children it is never so generalised or so scaly as in the adult. He believes every case of psoriasis in the child is due to rheumatism, and this cause is often overlooked owing to the peculiar manifestations of that disease in the young subject. He has been able to satisfy himself that in the greater number of instances psoriasis is merely a rheumatic manifestation, and he quoted two cases of psoriasis occurring in children who at the same time suffered from rheumatism and chorea. He accordingly treats every case of psoriasis with large doses of salicylate of soda or preferably aspirin. Alkaline baths and tar ointments are useful additional measures.

Drs. SPRIGGS and HIGGS showed a case of

HEMIPLEGIA IN AN EPILEPTIC

æt. 4 years, with athetosis of the arm. The hemiplegia was discovered one morning, the child having had a

fit during the previous night. The leg improved rapidly, and in two or three months he could get about. In July this year athetosis was present in both arm and leg, and it has persisted to the present time, being much more marked in the arm. There is weakness of the left side of the face and some mental impairment. The athetosis increases during excitement and ceases during sleep.

CONGENITAL DIVISION OF THE CLAVICLE INTO TWO PARTS.

A patient, æt. 12, was shown by Dr. SPRIGGS with the above deformity. Each clavicle consists of two pieces about 1½ inches long, connected together by a freely movable joint. At rest the pieces form a wide V with the apex upwards. The shoulders can be brought almost to meet in front. The X-rays showed deficient ossification of the bones; and Dr. Spriggs suggested that the ossification of the membrane bone was absent, and the two fragments represented the ossification of the two pieces of cartilage which take part in the development of the clavicle.

A CASE OF BRONCHIECTASIS IN A YOUNG CHILD was shown by Dr. WHIPHAM. The patient, æt. 2 years and 4 months, showed signs of well-marked bronchiectasis chiefly in the base of the right lung. Fingers and toes were clubbed. The condition seemed to be due to bronchitis and pneumonia, which was immediately followed by whooping cough.

LATERAL CONGENITAL FISTULÆ IN THE NECK, in a girl, æt. 8½ years, was shown by Mr. PHILIP TURNER. They were situated at the inner border of the sterno-mastoids, 1½ inches above the clavicle. The sinuses could be felt extending upwards nearly to the angle of the jaw.

A child with a large RETRO-PERITONEAL DERMOID TUMOUR OR TERATOMA was brought forward by Mr. RAYMOND JOHNSON. The tumour was in the upper left half of the abdomen, and resembled a sarcoma of the kidney. The lumbar spine was curved to the right, and in the left loin were two small fluctuating swellings apparently not connected with the abdominal tumour. A portion of a small cyst was removed and showed the naked eye and microscopic appearances of a dermoid.

Dr. POYNTON showed a girl, æt. 7, with œdema of the left lower extremity and labium.

Three cases of INFANTILE PARALYSIS were shown by Dr. GEORGE CARPENTER. One of them was a boy, æt. 11, with double foot drop of sudden onset; the muscles of the front of the legs gave the R.D. reaction.

Another case was in a girl æt. 3, who suddenly became paraplegic. The muscles of the legs and thighs gave the R.D. reaction. The child also could not raise the head or hold it erect, but she could move it from side to side.

The third case was in a girl, æt. 20 months, whose right leg was paralysed and the muscles gave the R.D. reaction. The left leg was rigid and its muscles reacted to Faradism, though feebly. The onset was sudden, after an attack of diarrhœa and vomiting.

SYPHILITIC NEPHRITIS in an infant æt. 3 months was shown by Dr. CARPENTER. The child was dropsical, the urine albuminous, and contained blood corpuscles and hyaline epithelial and granular cysts. The infant was well nourished, but had chronic snuffles, with nasal mucopurulent discharge and a fading eruption on the buttocks, backs of thighs and calves. It had improved by mercurial treatment.

The cases were discussed by the Chairman, Drs. Poynton, Spriggs, Carpenter, Porter Parkinson, and Messrs. Raymond Johnson and Jaffrey.

THE Conference of representatives of Hospitals from various parts of the kingdom will take place at 2.30 p.m. on Thursday, December 6th, at University College, London.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING AT SHEFFIELD ON FRIDAY, NOVEMBER 16TH, 1906.

MR. R. FAVELL (Sheffield), President, in the Chair.

FIBROIDS AND PREGNANCY.

MR. FAVELL showed a seven months' pregnant uterus containing fœtus and placenta with a fibroid which had completely blocked the pelvis. The abdomen was opened during labour and after the fibroid had been enucleated it was found necessary to complete the operation by supra-vaginal hysterectomy.

Dr. H. BRIGGS (Liverpool) showed a fibroid enucleated from the front wall of the uterus when four and a half months pregnant. The bleeding could not be controlled until the uterus had been emptied through an incision in the tumour bed, after which sutures were effective.

Dr. BRIGGS also showed a large fibroid removed at the third month of pregnancy from the anterior wall of the uterus. In this case bleeding was easily controlled and pregnancy was not interrupted by the operation.

ECTOPIC GESTATION.

Dr. H. BRIGGS showed an ectopic gestation removed six weeks after full term. The sac was dissected off the rectum and two inches of ureter had to be freed from it, and great care was demanded in the subsequent peritonisation of the pelvic floor and viscera. Recovery was good.

Dr. MACGREGOR SINCLAIR (Burnley) showed three specimens of early tubal pregnancy.

CARCINOMA OF OVARY AND UTERUS.

Dr. W. K. WALLS (Manchester) mentioned a case in which a large solid tumour of the right ovary was removed. This proved to be a carcinoma, and metrostaxis continued. The abdomen was therefore reopened, the uterus was removed, and its body was found to contain a carcinomatous growth.

CÆSARIAN SECTION FOR OSTEOMALACIA.

Dr. P. BARBER (Sheffield) demonstrated a patient, æt. 36, 4 feet 6 inches in height, who had had seven pregnancies. Her history and measurements were typical of osteomalacia, though a woman of English race who had never suffered privation. The seventh pregnancy was successfully ended by Cæsarian section. Both ovaries were removed, and the patient's health has much improved since the operation.

HELIOTOMY.

Dr. A. J. WALLACE (Liverpool) described two cases of pelvic contraction in which the Cæsarian section was contra-indicated, and in which he had therefore divided the pubic bone to the left of the pubic symphysis. The children were both delivered alive with forceps. Considerable separation of the bones was observed. There was severe bleeding in the first case, and extraction was troublesome in the second, the cut end of the bone wounding the vaginal wall. Dr. Wallace was not favourably impressed with the operation, though recovery was satisfactory in each case.

Dr. A. W. W. LEA (Manchester) gave an interesting account of the work of the Section of Obstetrics at the Canadian Meeting of the British Medical Association.

Mr. FAVELL, the President, subsequently entertained a large number of members and friends at dinner. He was supported by Sir W. J. Sinclair and Dr. D. Lloyd Roberts. The latter, in proposing the health of the host, expressed the affection with which the President is regarded, while Mr. Favell's reply was most happily worded, and was received with enthusiasm.

LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD NOVEMBER 2ND, 1906,

The President, Dr. J. B. BALL in the Chair.

The following cases were shown:—

THE PRESIDENT.—A case of Tumour of the Pharynx of about the size of a tangerine orange, pushing forwards

the soft palate. The tumour was of solid consistence; on the external surface, just behind the ramus of the lower jaw, there was a distinct hard swelling, apparently continuous with the tumour inside. The patient had no pain and only a little difficulty in swallowing food, and occasionally slight difficulty with her breathing.

MR. BUTLIN considered the case was operable, and advised that the tumour be removed.

THE PRESIDENT also showed a man æt. 52, with a swelling over the left arytenoid region extending upwards along the ary-epiglottic fold, the lateral folds of the pharynx were also thickened.

DR. JOBSON HORNE cited a case which presented similar clinical appearances in the larynx, and which succumbed to chronic interstitial nephritis; at the post-mortem examination there was found below the swelling of the arytenoid and situated in the fold between the cartilages of Santorini and Wrisberg a minute ulcer leading down to commencing necrosis of the underlying cartilage.

DR. ST. CLAIR THOMSON shewed two cases of Extensive Tuberculous Laryngitis which had completely healed, and had remained healed for some time, without any local treatment. It was, moreover, noteworthy that neither of the cases had undergone treatment in a sanatorium. In the discussion which followed there was a general consensus of opinion, and several cases were cited, that good and similar results were obtained by rest without any local interference with the larynx.

DR. H. J. DAVIS shewed a case of Stenosis of the Glottis, with Dyspnœa and Stridor, with a history of four previous attacks of pleurisy and of physical signs in the left lung. The evidence was considered to be in favour of tuberculosis.

DR. WATSON WILLIAMS shewed a case of Epithelioma of the Larynx. Dr. ST. CLAIR THOMSON also one of Malignant Disease of the Larynx, and Dr. DUNDAS GRANT a Glosso-Epiglottic Growth believed to be Sarcoma. These three cases were discussed together; the disease was in all three cases at the base of the tongue and upper part of the larnyx. In two of them the glands were involved, but probably within the reach of an extensive operation.

MR. BUTLIN was of opinion that an operation should be performed in all three cases. It should comprise removal of the contents of the anterior triangle on the affected side, of ligature and removal of the external carotid artery and all its branches. It would be well to remove at the same time the external carotid artery and its branches on the other side of the neck. A few days later the removal of the primary disease could be performed with scarcely any hæmorrhage and as freely as might be desired.

THERAPEUTICAL SOCIETY.

MEETING HELD NOV. 20TH, AT THE APOTHECARIES' HALL, LONDON.

The President, Dr. T. E. BURTON BROWN, in the Chair.

The following papers were read:—

Dr. CECIL WALL:

"THE VALUE OF CERTAIN DRUGS IN THE TREATMENT OF CHOREA."

The author remarked that several hundreds of cases of chorea had been treated systematically, both as in and out-patients, at the London Hospital; one group had had no special drugs; another had had arsenic; another, sodium salicylate; and a fourth group, aceto-salicylic acid (aspirin). The effects of the different kinds of treatment were compared, the criterion being the number of weeks before the choreic movements ceased. The figures were very striking, and showed clearly that under arsenic the course of the chorea was practically the same as without any drugs at all; with sodium salicylate the results were little better; whilst with aceto-salicylic acid the shortening of the attack was very remarkable: in half the cases the movements ceased in less than one month. In 92 per cent. of the cases in less than two months; whereas with arsenic the movements went on for over two months in 62 per cent. of the cases. There had been no ill-results at all.

Dr. GRAY DUNCANSON laid stress on the excellent results afforded by arsenic in chorea in the North of England, and thought the absence of similar results in the South must depend upon some difference either in the chorea, or more likely in the temperaments of the children affected.

Drs. Burton Brown, Parker Douglas, and Herbert French also joined in the discussion.

Dr. A. F. HERTZ read a paper on the

"IMPORTANCE OF SALT-FREE DIET IN THE TREATMENT OF ŒDEMA AND SEROUS EFFUSIONS."

This communication embodied so much work, and such important deductions, that it is impossible to do it justice in a short abstract. The orginal paper must be consulted when it is published in due course.

Drs. Parker Douglas and Dickinson joined in the discussion.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

FRANCE.

Paris, Nov. 25th, 1906

AT the meeting of the Société Internationale de la Tuberculose held last week under the presidency of Prof. Lancereaux, the subject of

COMPULSORY NOTIFICATION OF TUBERCULOSIS

was brought forward by Drs. Samuel Bernheim and Louis Dieupart. The authors, after having referred to the conclusions of the recent International Conference on tuberculosis (at the Hague, in October, 1906) and the favourable report of the committee of the Academy of Medicine (June, 1906) declare: "That prophylaxy cannot become real and efficacious unless the compulsory notification of tuberculosis is legally enforced. In a struggle with such a formidable enemy, no half measures will avail. The compulsory notification of tuberculosis could be made without any shock to humanity. Certain countries have adopted it, and find the advantage of it. We must await the day when the public in all countries will be sufficiently educated to accept this excellent measure of protection unhesitatingly. Compulsory notification, of course, involves, *ipso facto*, compulsory disinfection. According to Messrs. Bernheim and Dieupart, compulsory notification during the lifetime of the patients should only apply to manifest tuberculosis in which the patient expectorates the bacilli. It appears to them needless to complicate the matter by including all forms of osseous ganglionic. cutaneous, and other forms which rarely present any danger.

At the same meeting, the

PHOSPHO-CREOSOTE TREATMENT OF TUBERCULOSIS

was introduced by Dr. Samuel Bernheim. He remarked that demineralisation is a characteristic of the tuberculous subject. The soil is poor in phosphates and chlorides. This tuberculous soil is a hypo-acid and a hyper-comburant. The best treatment consists in transforming this soil and in assimilating it, as far as possible, to the arthritic formula. The hygieno-dietetic treatment does this admirably. But this treatment is peculiarly facilitated, and its duration may even be abbreviated, if accompanied by certain medical treatment, especially phospho-creosote therapeutics. There is a poly-ether of creosote which facilitates this transformation of the tuberculous hypo-acid soil into arthritic hyper-acid soil, and this is phosphite of creosote of "Phosphotal" This salt acts both by its phosphoros acid, in removing the humoral acidity, by its phosphoric element, in combating the de-phosphorisation of the tuberculous soil and in replacing it by an arthritic soil, and finally by its

creosote, an acidifying medicament which liquefies the expectoration and especially influences the bacteria associated with the bacillus, which will decrease, and often disappear.

The author has treated a large number of tuberculous subjects with Phosphotal, and he particularly notes 97 cases most of which have derived benefit from this treatment. Phosphotal, which is easily tolerated, is administered *per os*, by subcutaneous injections, or by the rectum, in daily doses of 0.50 centigrammes to 2 grammes. This treatment may be continued for a very long period without the slightest inconvenience; an interval of eight days should be allowed after administering Phosphotal for three weeks.

Pneumonia.

According to M. Musciangoli, sulphide or carbon possesses real efficacy in the treatment of acute pneumonia. A purgative is at first administered, and the following day he gives a tablespoonful every hour of:—

Sulphide of Carbon .. .. 1 drachm.
Peppermint water .. .. 4 ounces.

Four children treated thus by the author were cured in from one to three days.

Pleurisy and Pilocarpine.

A doctor relates that, called to a patient suffeeing from a large effusion into the pleura, thoracocentesis was advised but the patient refused it from pusillanimity, and injections of pilocarpine were substituted with complete success. The dose employed was one-fifth of a grain. and the injections repeated every day for a week, at the end of which time the effusion had disappeared.

GERMANY.

Berlin, Nov. 25th, 1906

At the meeting of the Medical Society Dr. Rothschild showed a young man æt. 21, who for some weeks before had persistent and severe pains in the perinæum and base of the penis, which had reduced him to a very low condition, and there was also persistent dribbling of urine. The urine contained pus and blood, and there was also some blood from the anus. A Nelaton catheter passed quite easily. The bladder would not hold more than 30 cm. (1 oz.) of fluid. Under treatment with narcotics and washing out of the bladder, the urine gradually cleared and the capacity of the bladder increased, but the pains still continued and some blood still came now and then from the perinæum. At this period the patient, who had been repeatedly questioned, stated that some time previously he had passed a tube containing wax into his urethra. When the tube was withdraw the wax remained. Röntgen illumination now showed concrements. Sectio alta was performed, the calculus removed, and the bladder closed by suture. The result was good.

Exz. v. Bergmann reported shortly the case of a patient suffering from

Stricture of the Urethra

with retention of urine. After gradual dilatation of the stricture a stone was accidentally felt, the origin of which was paraffine that had got into the bladder. In Brussels a woman had tried to relieve the stricture by injecting paraffine.

Hr. Cryilletzer related a case of

Widespread Injuries through the Electric Current.

In a factory very strong currents were employed, in which the very strong iron parts inserted in current circle were cut through by a very intense and hot arc light from carbon points. This work was carried on in the open in a corner of the workyard. Five yards away from this was the path leading to the closets. Of the workpeople who had passed along the path, not as engaged at the work in question, but merely passing to and from the closets, twelve were taken ill the following night with violent pains in the eyes. All twelve came the following morning to the speaker, and all complaining of the same troubles. All had intense pain, photophobia, swelling of the conjunctiva and of the eyelids. One of them had slight clouding of the cornea. The refracting media were intact, and there was slight reddening at the fundus. The cases were well-marked ones of ophthalmia electrica. In a few days the trouble disappeared. From these occurrences it behoved to take precautions at such works to protect not only those who worked at them, but others who only had to pass near them.

It was not the heat rays that had caused the ophthalmia; the workmen working at the job in question were not affected, but only those who passed by at some little distance away. It must have been the ultra-violet rays, and in favour of this assumption was the absence of after-images, of which not one made any mention.

Hr. Hirschberg was of opinion that all rays might be injurious to the eyes, and care should be taken to protect them in all dangerous occupations.

Hr. Oppenheim showed a case of

Occipital Tumour of the Brain Cured by Operation.

A merchant, æt. 35, was taken ill in March last with pains in the head, especially the back of it, the neck and back. When seen on April 25th an examination of the nerve system showed nothing. On May 8th there was hæmorrhage into the retina of the left side, some days later optic neuritis of the same side, and distinct slowing of the pulse. Then came on vomiting, bilateral choked disc, hemianopsia of the left side, and visual hallucinations, as well as alexy and agraphy. The speaker made a diagnosis of tumour of the posterior lobe of the brain, and as mercury and iodide did no good, he at once decided to operate. The operation was performed by F. Krause, who found a tumour in the posterior part of the posterior lobe that could be shelled out. At first the optic hallucinations got worse after the operation, but they soon became fainter, and gradually all the symptoms disappeared, the hemianopsia as well, so that complete recovery took place.

Hr. Krause said that the tumour, a spindle-celled sarcoma, was an encapsuled one the size of a pigeon's egg. It lay near the mid line in the left posterior lobe, and extended to the cuneus. It was shelled out without any hæmorrhage. After the operation there was high temperature, but this did not mean fever, but was only a result of the operation in the immediate neighbourhood of the medulla oblongata. Recovery was uninterrupted.

Health Statistics in Prussia for 1904.

This report has just mads its appearance. It is compiled in the department of the Mimister for Spiritual, Medical and Educational Affairs, and published by R. Schoetz. The number of births for the year was the highest ever known, and reached a total of 1,304,697, showing an increase of 30,031, of which 29,321 were living children. The proportionate rate of birth was 35.04 per 1,000. This is below the figure, for 1901 and 1902, but a little better than 1903. The absolute number of deaths was 702,147, 5,803 less than the previous year. The death-rate per 1,000 inhabitants was 19.46, whilst the death-rate for 1903 was 19.9. The worst figures come from Silesia, with a death-rate of 24·16 per 1,000, and the most favourable from Schleswig-Holstein, 15.97 per 1,000. One-third of all the deaths were in infants under one year of age.

The Treatment of Nasal Catarrh.

The *Deutsche Med. Zeitung*, No. 85, contains a reference to the subject from the pen of Dr. Zäslein. It is well known that a nasal catarrh often leads to mischief elsewhere, and that many cases of bronchitis linger on for weeks for the reason that a nasal catarrh continues to furnish ever fresh infective material. It is desirable, therefore, to treat the nasal cavity as energetically as possible. The methods hitherto employed, such a douches and snuffing powders, are very little or no good, as the nasal mucous surfaces cannot bear powerful antiseptics. Incomparably better results have followed the use of solutions of

collargol, ½ to 1 per cent. solutions applied 6 to 8 times a day to all three nasal canals of both sides, blown in by a pulverisator. If the circulation in the nose is impeded by scabs or swelling of the mucous membrane, cocaine and menthol nasal powders should be made use of before applying the collargol. In this way the secretion dries up rapidly. If there is angina as well, gargles with a 2 per cent. solution of collargol may be made use of.

THE TREATMENT OF RECENT WOUNDS BY DRYING.

The *Munch. med. Wochensch.*, 42, 1906, contains a paper on this subject by Dr. Asbeck. The author, who is a naval surgeon, was in the habit of placing the freshly-wounded in the hot sun on the deck, and in this way got his dressings dried rapidly in the tropical heat. The wounds healed without suppuration or change of dressing in a few days. On days when there was no sun he dried them by the heat of the boilers.

Every recent injury was, without disinfection of the surrounding parts or being touched with the hand, covered with an iodoform gauze compress, kept in place by a few layers of gauze. Over this cotton-wool was placed (lint or gamgee), and the whole fixed with a gauze bandage. In the case of burns the blisters were removed with scissors and forceps, and the part covered with iodoform gauze. Of course the greatest care was observed as regards asepsis.

The wounded so dressed were now subjected to the glowing heat of the boiler for from a half to three-quarters of an hour, whereby an "intensive" drying was achieved. If the covering got wet with later hæmorrhage from the wound, a new layer of gauze was simply put on and dried as before. In these cases also healing took place in a few days.

This method was tried in about 500 recent injuries and with satisfactory results. For drying-up he used whatever heat was handiest—furnace boilers, the smith's fire, the Bunsen burner. Later he used xeroform gauze in place of iodoform, and when removing this a 2 per cent. perhydrol (Merck) was used. Eleven gunshot wounds treated in the same way healed without suppuration.

AUSTRIA.

Vienna, Nov. 25th 1906.

SYPHILIS IN THE CRANIUM.

EHRMANN presented a case of excessive tertiary syphilis. The whole scalp was raised up from the periosteum by an enormous infiltration. Its progress was serpiginous, with a garland appearance at the base of a brown infiltrate, showing that it was not scrofulous but gummatous in nature, having all the appearance of an untreated tertiary case.

Lang thought these cases mostly ran a very favourable course, although great destruction was often done before they healed. He had a female with the whole scalp lifted, and an opening in the calvaria about the size of the palm of the hand that had been eaten away through the lamina vitrea to the dura mater, so that the pulsation of the brain could be easily perceived. To protect the soft substance from protruding, an aluminium plate was applied with excellent results.

Marack thought Erhmann's case now required strong prophylactic treatment.

APPENDICITIS AND EXTRA-UTERINE PREGNANCY.

Fabricius showed a few preparations where extra-uterine pregnancy had been diagnosed for appendicitis and *vice versa*. Along with these complications, a myoma in the right iliac fossa added to the difficulty. In another case of extra-uterine pregnancy he found the gravid tube adherent in the pouch of Douglas flattened and immovably fixed. In another case he met with a six weeks' pregnancy in a severe case of appendicitis. In this case the fœtus was pressed quite flat and scarcely recognisable in the diagnosis. The importance of the latter case lies in the danger of the ovum bursting and doing fatal injury.

INTERNAL CHRONIC IDIOPATHIC HYDROCEPHALUS.

Fuchs demonstrated a case of interesting hydrocephalus in a child. His examination of the eyes showed that both papillæ were greatly congested, and far advanced in atrophy. There was also distinct exophthalmia present, but all the reflex organs were healthy. The nerve system was apparently healthy, with the exception of a blowing sound in the head, which was objective. To ascertain with accuracy the otoscope was used, and found the blowing greater on the right side than the left. This blowing sound synchronised with the systole, which could be modified or destroyed by compressing one or both carotids.

Was this a tumour or aneurysm of the brain? The relative youth of the patient was against this hypothesis. The congested papillæ was also a negative sign, as this rarely occurs in endocranial aneurysms. His own opinion was that this was a case of hydrocephalus idiopathicus chronicus internus of the adult, which is slow and intermitting in its progress. The intermitting blowing sound in the head was another confirmatory factor in the case.

Frey thought that our present knowledge received very little assistance in the diagnosis from this objective rushing sound.

Schlesinger thought the youth of the patient was no argument against the presence of aneurysm. This affection is relatively more common in youth than in the adult, and therefore a strong proof of the affection being an aneurysm.

CEREBRAL TUMOUR.

Flesch showed a preparation taken from the *post-mortem* room that confirmed the diagnosis. The growth extended from the sphenoid bone along the left side of the head to the middle of the occipital.

PSEUDO-MENIERE.

Frankl-Hochwart showed a patient with vertigo resembling that met with in Meniere's disease. These attacks occurred daily, or at least several times a week. Immediately before the attack, and sometimes during the attack, a loud rushing noise is experienced in both ears. During the invasion all went round, sometimes to the right, sometimes to the left; he could either stand or sit, and never lay down; neither did he close the eyes. Morbus Basedowii was present in a slight degree, but the most interesting point was that exacerbation of the ear and vomiting during the attacks had all the symptoms of Meniere disease. Against genuine vertigo auralis is the negative condition of the ears and the circumstance that the patient can stand upright and also not close the eyes. Hochwart considered it one of pseudo-Meniere.

GANGRENA PEDIS.

Schwarz referred to Moszkowicz's intermitting halt as a prodroma of gangrene. He was disinclined to accept this opinion in the early stage of the disease, as any insufficiency of the artery such as sclerosis of the wall of the vessel when the muscle is exercised will produce severe spasm just in the same way that angina pectoris is produced when the coronary arteries of the heart have become sclerotic. In such cases Moszkowicz's symptom would be misleading.

Moszkowicz admitted the confusion that might arise in the diagnosis if intermitting lameness was accepted as pathogenic. The point he wished to demonstrate was the hyperæmia after the binding and freeing of the extremity. The intermitting lameness appears in some cases, but not in all.

HUNGARY.

Budapest, Nov. 25th, 1906.

AT the recent meeting of the Royal Hungarian Medical Society, Dr. Altmann exhibited a man, æt. 60, with

MULTIPLE LIPOMATA OF THE NECK.

The patient first noticed these tumours nine years ago. At first they annoyed him on account of the pressure which they made upon his collar button. The tumours at that time were about the size of a pea, but within a year or so they had attained their present size. The patient had not found it necessary, however, to wear a collar of larger size on account of the tumours. At the time of the incision, there was no attempt made

to remove the entire tumours, but only portions of them were taken away. This operation was done by another surgeon. The tumours had been practically stationary in size for five years. Dr. Altmann stated that symmetrical lipomata of the neck region were not very rare, but that this was a pronounced case. Patient had large lipomata in front of the neck, which, he said, was not an unusual concomitant of such cases.

Dr. Aczél read a paper on

HYPODERMOCLYSIS IN PNEUMONIA.

In spite of all the innovations which have been made in the treatment of pneumonia, the death rate has been very little changed during the past three or four decades. Statistics, however, in such a disease as pneumonia, in which so much depends upon the age, the previous habits and condition of the patient, and the "genus epidemicus," are not only not infallible, but often misleading. Dr. Aczél applies hypodermoclysis, as recommended by Henry, in such cases. He believes that hypodermoclysis is theoretically indicated in every case of pneumonia, although he does not employ it in many mild cases. It dilutes toxins and favours their elimination; it preserves the alkalinity of the blood, which is one of the most important properties of the vital fluid, and, finally, certainly tends to prevent the formation of heart clot, which the writer believes to be a frequent cause of death in pneumonia. The solution employed contains 2.50 grammes sodium chloride to the pint of distilled and sterilised water. He uses a large syringe or chest aspirator, the action being reversed, and injects from 3—4 litres once a day.

Dr. Veress spoke about the Toxic Agent of Cholæmia. Icteric patients sometimes develop an alarming series of cerebral symptoms which usually end in coma and death. The direct cause has frequently been a matter of speculation, and it is as yet undecided whether the bile pigments, bile acids, or the loss of hepatic function are at fault. Dr. Veress noticed a close resemblance to diabetic coma, and concluded that the whole condition is an acid intoxication. The common bile-duct was ligated in a number of rabbits and the blood titrated every day until death, which generally occurred on the fifth or sixth day. The alkalinity gradually diminished day by day, but not to a sufficient degree to account for the symptoms on the basis of an acid intoxication. The amount of carbon dioxide was also found considerably below normal. Since animals with much less alkali have been known to live for days, probably other facts bring on the fatal issue.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

THE GENERAL MEDICAL COUNCIL ELECTION.

DR. BRUCE has issued an address to the practitioners of Scotland, of which the following are his leading points:—After alluding to the fact that for twenty years he has endeavoured to discharge the duties of his position as direct representative for Scotland to the satisfaction of his constituents, and with a single eye to the interest of the medical public, is strongly of opinion that the profession is not fully enough represented at present in the Council, and his first efforts, if re-elected, will be directed to induce the Council to enlarge the present number of representatives selected directly. Failing to get the Council to take up the duty, he proposes, along with his English and Irish colleagues in the direct representation, to petition the Privy Council to solve the difficulty. As regards medical education and training, he holds strongly that there should be more practical and clinical work than there is now. In particular, he says, the great department of midwifery is not taught as it should be. Clinical attendance at a lying-in hospital ought to be compulsory. The present medical curriculum much requires to be lightened in its first stages by relegating botany, physics, and biology to a *preliminary* science examination. In this way more time could be devoted to general clinical work, as also to special subjects, such as psychology, eye, ear, throat, and skin diseases He would also assist in any effort dealing with the sale of patent medicines, in reform of hospital abuse, and in maintaining the reputation of the profession by discountenancing, so far as the Council can, contract medical practice.

Considerably more interest is being taken in this than in the last election of a direct representative. Dr. Walker has addressed several meetings in various towns in support of his candidature, and has issued, as an election address, a report of his first speech in Edinburgh, to which we have already fully referred. Some attempts have been made to make it seem as though by the return of Dr. Walker, Edinburgh would be unduly favoured in the matter of representation on the Council, as compared with Glasgow. This is surely merely playing upon the local jealousy which, unfortunately, still exists between the two cities. If Dr. Walker is elected his Glasgow constituents need not fear that he will in any way subordinate their interests to those nearer his home, nor in any way neglect them.

AN IMPORTANT VACANCY AT THE GLASGOW ROYAL INFIRMARY.

The directors of the Glasgow Royal Infirmary are at present advertising for a physician to take charge of the wards vacated by Dr. John Lindsay Steven, who, it will be remembered, was transferred to the Western Infirmary to succeed the late Dr. James Finlayson. Candidates for the appointment must have been registered practitioners of ten years' standing. We understand that Dr. Hugh McLaren and Dr. Mackenzie Anderson, both of whom have been assistant physicians, are applicants. Dr. McLaren is conducting the work in the wards at present, and has had considerable experience of pathological work. At present he is the Professor of Materia Medica and Therapeutics at Anderson's College of Medicine.

LETTERS TO THE EDITOR.

THE GENERAL MEDICAL COUNCIL ELECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The quiet, contemplative and reasonable letter of Dr. Crichton, which you published on the 14th inst., is somewhat contagious, and one feels tempted to review this election contest in somewhat the same manner. There certainly seems to be more excitement this time than previously; whether it will result in a larger poll remains to be seen. Those who see only the *British Medical Journal* would naturally expect that its candidates will carry all before them. But the ground covered by that journal does not embrace the whole medical world, and well is it that this is so, inasmuch as it appears to become more cliqué and narrow-minded as time progresses. I shall be glad, therefore, if you will permit me as an elector to take a dispassionate view of the candidates and their claims to support.

Beginning with the two existing members of the General Medical Council, Messrs. Brown and Jackson, it is, of course, uncertain whether they will retain their seats, so many changes having taken place since their election five years ago. There has been the new constitution formed of the British Medical Association, which is responsible for much of the hubbub now going on; hence a calm review of the situation is essential on the eve of the election. Even your correspondent Dr. Crichton does not recognise that there are any burning questions at issue between the candidates, and doubtless there are many others who view the matter in the same light.

To my mind the main question is contract practice, as applied to provident dispensaries and clubs. This is and has been a growing evil for many years, and is sapping the very life-blood out of our daily life. Its

ramifications are enormous. A decent man may commence practice in many places, and sedulously follow out the best traditions of the profession; yet he will remain months and months without patients. And why? Because the place is honeycombed with clubs and dispensaries.

And I am sorry to say the British Medical Association itself is infected, and very largely, with this evil. Many, if not most, of the active men at headquarters are pushing it for all they are worth, through a public medical service, which will mean more riddling, more honeycombing of general practice, and with all the sanction and *éclat* of that great association.

The question naturally follows—what, then, are we to do as electors? According to my opinion, there is one candidate who seems specially fitted for this task, and that is, Dr. G. H. Broadbent, of Manchester, who has had, as we read in his address, special training for this work. Years ago he was on the staff of a dispensary, and fought for a wage limit, and when he could not get it, he left that institution, and is still fighting for this point. He is the candidate for whom I shall vote, and I trust thousands of others will view this election from my standpoint. But the great danger is the apathy of the electors at large, especially of those who are not members of the British Medical Association. If all will record their votes as soon as they receive the ballot paper, this election will at least show that the profession has arisen to the full discharge of its duties when a great occasion demands.

I am, Sir, yours truly,

AN ELECTOR.

Manchester, November 24th, 1906.

*** On account of the extreme length of our correspondent's letter, we have been compelled to reduce it very considerably.—ED. "M. P. and C."

THE CANDIDATURE OF MR. J. RUTHERFORD MORISON.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—By this time the practitioners who take any interest in this election must be pretty well posted up in the merits of the respective candidates. We do not propose, therefore, to do more in this last word on Mr. Morison's behalf than to answer the only objection—if, indeed, it can be dignified by that name—to his candidature. He is accused in some quarters of being a consultant, and to this he must plead guilty. To the general practitioners of the North, who know Mr. Morison best and have deliberately chosen him on this as on many other occasions to be their representative, the fact of his being a consultant, with his previous record of 13 years in general practice and his work for us since he became a consultant, seems to give him a peculiar claim on the support of the profession, as he is enabled to look at all medical questions from both sides. We know where his sympathies lie, and with the record of Sir Victor Horsley before us, we are not to be made ashamed of our candidate because he does not now happen to be in general practice.

We would earnestly appeal to the profession to distribute their votes, other things being equal, with some reference to the geographical distribution of the candidates. The medical men in this part of the country have pretty generally made up their minds to vote for Messrs. Morison, Browne, and MacManus on the grounds that these gentlemen are thoroughly good candidates and represent broadly the North, Midlands, and South. We appeal finally for such a vote, however distributed, as will once for all end the cry that medical men take no interest in their own business.

We are, Sir, yours faithfully,

E. JEPSON, Chairman.
ALFRED COX,
H. HUNTER,
Honorary Secretaries to Mr. Morison's Committee.

Cotfield House, Gateshead, November 19th, 1906.

THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is impossible to exaggerate the importance of this subject; and if you and your readers are not for the moment tired of it, you may care to note the last phase of the question in France. French statistics for 1905 show that whilst marriages increased comparatively, births fell off, the rate being the lowest on record. In forty-four departments—as compared with thirty-six in the previous year—the deaths were in excess of the births; and in certain provinces the difference was enormous—three deaths as against two births. It must be borne in mind that the population has remained stationary since 1871, although every intelligent Frenchman has known that their national safety has depended all along upon due increase of numbers. Prudence, which may at first have formed a plausible excuse for restricting the number of children, has universally deteriorated into a narrow form of selfishness, unmoved even by the call of patriotism.

It would require an essay to examine the effects upon parents and offspring, among those classes able to support a larger family, where the number of children is restricted to two or three, but these effects are to be learnt from a study of contemporary French literature, and unquestionably suggest extensive progressive decadence. There may, of course, be grounds for controversy in this direction, but there can be no dispute about the main fact that, viewed from the international point of view, the French are committing deliberate race suicide, or, as it is now styled, more appropriately, *felo de se*. It would be interesting to learn from Dr. Drysdale and his fellow-protagonists of the cult of neo-Malthusianism, what grounds they have for the belief that the British people will show more restraint than their neighbours, and will think more of the preservation of their country, and the creation of a truly mighty empire than of their own narrow egotistical desires. Is it not certain that in imitating the French we have entered upon a slippery path which, unless the soul of the nation can be speedily roused, will land us in the abyss towards which our neighbours have already far progressed, and seem now inevitably bound.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

November 23rd, 1906.

PROSPECTS OF MEDICAL LAW REFORM.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The editor of the *British Medical Journal* gravely rebukes a correspondent for his ignorance of the fact that the Association has been engaged in drafting a new Medical Act. It is one thing to draw up a project of law quite satisfactory to experts outside Parliament; quite another thing to get the project accepted by the Legislature. It is easy to "call spirits from the vasty deep; but will they answer when you call on them?" Does anyone believe that the present Government is in the least likely to take up, and endeavour to pass a Medical Act satisfactory to the profession? Does anyone acquainted with the legislative machinery of the present day, and informed as to the attitude of individual members, and the House of Commons as a whole, towards the profession, believe that a new Medical Bill would have the remotest chance of serious attention if introduced by a private member, however distinguished, without the support of the Cabinet? Does anyone acquainted with the glaring facts of the case doubt that introduction of a new Act by a medical member would suffice to ensure a hostile reception, and opposition more than sufficient to wreck it? Medical sponsorship would inflame the ardour of all those who distrust the profession, of those who dislike it, and of those who associate it with the practices of vaccination and vivisection to combat which they devote their lives. The suggestion of selfish trade's union motives would be impossible to refute. The case for legislation cannot be made unanswerable until irrefragable proof has been afforded by means of a public enquiry

that amendment of the law is called for more for the protection of the public than the advantage of the profession, and the sooner this fact is recognised and acted upon by the British Medical Association the better it will be for the cause of reform.

I am, Sir, yours truly, S.

November 23rd, 1906.

OVERDOSAGE WITH TRIONAL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Noticing an editorial in your issue of September 26th on "Overdosage with Trional," I thought that a case which came to my knowledge in July, 1901, might be of interest.

The patient, a female, æt. 33, was at a seaside resort for her health, attended by a trained nurse. For several years she had been treated for various phases of nervous disorder, which frequently bordered upon melancholia. Trional had been prescribed for the persistent insomnia, in powders of grs. xxx., and she always carried a supply. Upon this occasion, wishing to put an end to her existence, she took ten of the 30-grain powders, very cunningly chewing up and swallowing all the papers but two, and these she threw into the wastepaper basket. The nurse coming up to see her some time later found her in a condition of stupor, and finding but two powders left in the box which had contained a dozen, grasped the situation at once, in spite of the two decoy papers in the basket. On my arrival the patient had stertorous breathing, well-marked cyanosis, pulse soft, weak, and slow, and she could just be aroused enough to swallow. Whiskey had already been given, and an emetic of Zn. Sulph. was very effectual; strong coffee was given and eventually retained. As the patient had an idiosyncrasy for strychnine, this was withheld, and aromatic ammonia and caffein citrate given instead. The pulse picked up rapidly, and in twenty-four hours most of the toxic symptoms disappeared, and the patient had so far returned to her normal condition as to express regret for her action, and explain why she had swallowed the powder papers.

The treatment may be criticised; but when on a holiday trip one has to take what is nearest to hand in an emergency, and the result could hardly have been improved upon.

I am, Sir, yours truly,

MALCOLM MACKAY.

Windsor Mills, Canada, Nov. 19th, 1906.

ANTI-VIVISECTION METHODS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—May I assure your correspondent "Physiologist" that all responsible Anti-vivisectionists deeply deplore the inaccurate and ridiculous statement which appeared—they know not how—in *The Tribune* about a cat jumping off the table in the course of vivisection by Professor Starling. This is a story which any Anti-vivisectionist who knows the conditions under which Vivisection is carried on would distrust from the simple fact that the details of the experiment referred to were supplied by Professor Starling himself, who was not likely to add such a sensational detail, even if it had been true. *The Tribune's* withdrawal was therefore not needed in our case to discredit the story. I can only suggest that it was either a practical joke carried out by some vivisectionist with a view to further developments, or the action of one of those irresponsible persons who unfortunately cannot be prevented from joining themselves to every public movement. It is certainly not a sample of the "Anti-vivisection methods" of the British Union, or, I think, of any other recognised Anti-vivisection Society.

I am, Sir, yours truly,

B. E. KIDD,

Secretary British Union for the Abolition of Vivisection,

32, Charing Cross, S.W.

OBITUARY.

GUSTAVE I. SCHORSTEIN, M.A., M.D., F.R.C.P.

LAST week we recorded the death of Dr. Schorstein, which occurred as the result of diabetes at the early age of forty-three. Dr. Schorstein had a brilliant career at Christ Church, Oxford, where he proved himself so accomplished a classical scholar that after graduation he was elected junior student and assistant tutor. Fond as he was of classics, however, his heart was set on medicine, and he left Oxford to study at the London Hospital. His keen intelligence and unusual energy there won for him the same distinction as he had gained at the University, and after qualifying and serving in junior posts, he was elected Assistant Physician. Soon afterwards he was appointed to a similar position in the Brompton Consumption Hospital, and at the time of his death he was full Physician to both institutions. To an enthusiasm amounting almost to a passion for his clinical work, Dr. Schorstein added rare personal qualities. His large-heartedness and overflowing good-nature made him immensely popular with everyone with whom he came in contact, and his tact never failed him even in dealing with the most dour hospital patient. Straightforward, honourable to a fault, and ever spreading happiness around him, Dr. Schorstein has left a place in the hearts of his friends and colleagues that can never quite be filled.

EDMUND SYMES THOMPSON, M.D., F.R.C.P. LOND.

WE regret to announce the death of Dr. Edmund Symes Thompson, on Saturday, at 33, Cavendish Square, London, at the age of 69. He was a son of the late Dr. Theophilus Thompson, F.R.S., an authority on pulmonary diseases. Dr. Thompson was educated at St Paul's School and King's College, and graduated as M.B. of the University of London in 1859, taking the University medical scholarship and gold medal. He took the degree of M.D. in 1860, became a member of the Royal College of Physicians in 1862, and was elected to the Fellowship of the college in 1868. He was appointed assistant physician to King's College Hospital and to the Consumption Hospital at Brompton, to which he was consulting physician at the time of his decease. He was also Gresham Professor of Medicine, and in that capacity delivered lectures for many years. Among his published works were "Observations on Influenza" and an edition of his father's Lectures on Pulmonary Consumption.

JOHN GREIG McDOWALL, M.D.EDIN

WE regret to note the death of Dr. John Greig McDowall, the medical superintendent of the West Riding Lunatic Asylum at Menston, of which institution he has been head ever since it was opened in 1888. Dr. McDowall died suddenly at the age of 55. A Scotsman by birth, he possessed rare tact and discretion, as well as considerable administrative nd organising ability. The asylum at Menston is the third of its kind in the West Riding, those at Wakefield and Wadsley (Sheffield) having been respectivelv completed in 1819 and 1874. Deceased was educated medically at the University of Edinburgh, where he took the M.B., C.M., in 1873, and the M.D. in 1883.

SPECIAL ARTICLE.

THE REPORT OF THE POOR-LAW REFORM COMMISSION (IRELAND).

THE first volume of the Report of the Viceregal Commission on Poor-law Reform in Ireland appeared at the end of October, and contains the text of the Report itself. Further volumes will consist of an "Appendix" and of "Minutes of Evidence and Index." The Commissioners, who were appointed by Lord Dudley in May, 1903, were Mr. W. L. Wicks, a member of the Local Government Board; Mr. George

Murnaghan, a Member of Parliament and chairman of a board of guardians; and Dr. Cory Bigger, one of the medical inspectors of the Local Government Board. Though they have spent over three years in their inquiries and deliberations, they certainly cannot be accused of having wasted any time. They inspected all the workhouses, county infirmaries, fever hospitals, and other hospitals in Ireland, maintained wholly or in part out of local rates. They visited and examined the circumstances of localities at a distance from any hospital, with a view of discovering whether further hospital accommodation is necessary. They examined 743 witnesses, and occupied 59 days in public sittings.

They have therefore made the most thorough investigation of the Poor-law system in Ireland which has been undertaken since its inauguration seventy years ago. Interpreting the terms of reference in the widest sense, the Commission has made recommendations, not of reform, but of revolution. There is no detail of the system too petty, no principle too great, for their investigation, and they have succeeded in formulating—whatever be its faults—a scheme at once comprehensive, rational, and thorough.

Our space forbids us following the Commissioners through their historical survey, or into the details of their study of every phase of Poor-law work. We can only touch on a few main points in their scheme of reform.

The workhouse system, as it has existed for two generations, should be entirely abolished. In order to make provision for the various classes of persons at present inmates of workhouses or workhouse hospitals, the following recommendations are made:—

1. The *sick* would be provided for in county or district hospitals. Sanatoria would be provided for the treatment of pulmonary tuberculosis.

2. The *aged and infirm* of a County or Counties would be placed and classified in the most conveniently situated disused workhouse, as a county or district "almshouse"; or boarded out in institutions such as those maintained by the Little Sisters of the Poor or the Sisters of Nazareth; or by the trustees of ordinary almshouses.

3. The *Insane* of all kinds in workhouses at present would be removed to lunatic asylums.

4. Two disused workhouses in Ireland might be set apart for the *sane epileptics*.

5. The *mothers of illegitimate children* should never be admitted or retained in any workhouse or institution where they would have freedom of ingress or egress, and where they could associate with other classes. Unmarried mothers should be provided for in special institutions under religious or philanthropic management, *their infants being kept with them until weaned*.

6. Nearly all *children* ought to be boarded out from (say) one year old up to whatever age it may be thought best to fix as a maximum limit of age for boys and girls respectively.

7. For *casuals and vagrants*, they recommend an institution (say *four* at first for all Ireland) to be called the "Labour-House," where, if they were found begging, or if they are dependent on the public for their support, they would be detained under order of a court of justice for long periods (say from one to three years), for the purpose of accustoming them to habits of sobriety, regularity, and industry.

8. As regards "*all other able-bodied*," they suggest that the really able-bodied loafing ne'er-do-well class be put with the casuals and vagrants.

The Commissioners believe that, apart from hospitals and asylums, only 63 buildings would be required for the above purposes. This includes an estimate of 12 sanatoria for consumptives. Obviously, no new buildings would be required, as there would be available a large number of disused workhouses.

The remarks on the present position of medical men in the Poor-law hospital service will attract attention, as will also the proposal to establish a State Medical Service. The witnesses referred to in support of the latter are Dr. Warnock, of Donegal, and Dr. Thompson, of Omagh. It is suggested that admission to the State Medical Service should be by competitive examination, on similar lines to the examinations for the Army, Navy, and Indian Medical Services. Admission should, however, be limited to candidates educated in Ireland. Control of the Service in all important matters should be in the hands of a Council of representative physicians and surgeons, nominated, for instance, by the professional colleges and the Universities. Pensions on the Civil Service scale should be the right of members of the State Medical Service. In this connection we quote one sentence:—

"One must acknowledge that at present there is not any motive except the very highest to encourage a medical officer in remote districts of the country to discharge his duties zealously and conscientiously, and in a manner worthy of the traditions, character, and obligations of the profession of medicine."

It is to be noted that the Commission regard the Dispensary Medical Service and Public Health Service as outside the scope of their inquiries, but their inclusion would facilitate the scheme.

The Report is unanimous, except as regards certain financial clauses, as to which Mr. Murnaghan differs from his colleagues.

LITERARY NOTES.

To medical men essentially it pertains to diffuse correct knowledge with regard to alcohol and its use in health. The views of the profession on the subject have undergone a radical and healthy change in the last quarter of a century, and there are already signs of a "wave of sobriety" coming over the nation. Those who wish to forward this movement can safely trust "The Alcohol Problem in its Biological Aspect," by Dr. Kelynack, a well-written, handy treatise for popular perusal.

***

A capital little book on "Local Anæsthesia in General Surgery" has just been written by Mr. J. W. Struthers, of the Leith Hospital and Royal Infirmary, Edinburgh. The range of utility of local anæsthesia has been enormously increased of late years, and for minor surgery in general practice the convenience of dispensing with a general anæsthesia is great. The various methods of inducing anæsthetic by local applications and drugs are concisely set out in this work.

***

Till lately Davos was held to offer one of the few chances open to the consumptive; but the home sanatorium must seriously have encroached on its popularity. Still, the climate and *entourage* of Davos have peculiar advantages for those who are well enough off to afford to winter there, and what these advantages are has been made the subject of a book. "Davos," by Dr. W. R. Huggard, and a staff of contributors. It should prove useful to medical men who have patients wishing to go there.

***

THE second edition of that practical handbook, entitled "Woman's Health and How to Take Care of It," by Florence Stackpoole, has just been issued by Messrs. John Wright and Co., of Bristol. Written by a woman for women on proper lines, it will naturally appeal to those for whom it is specially intended; but junior practitioners will find within this volume many useful hints as to the management of some of those apparently puzzling cases which those beginning practice are sure to encounter.

***

AN interesting little treatise has just been published by Messrs. Cassell and Co., Limited, entitled "The Health Reader," written by Miss Hoskyns-Abrahall. It deals in a popular way with matters affecting personal health. Among other interesting features are the illustrations of famous scientists, such as Lord Lister,

Pasteur, and Darwin. For use in schools this book is admirably adapted, and a knowledge of the principles which its authoress endeavours to teach will do much to make the homes of the people healthier and happier. It has our hearty commendation.

***

MR. LOUIS RAWLING, F.R.C.S., of St. Bartholomew's, has brought out a neat little Atlas of the Superficial Muscles and Nerves. The plan adopted is that of displaying the photograph of a posed living subject on one page with a facsimile drawing delineating the muscles and nerves on the opposite one. There are in all four such pairs of illustrations. The idea is a happy one, and it is well carried out. Art students should find the Atlas of great assistance.

***

WE have been asked to draw attention to the fact that Messrs. Alex. Thom and Co., Ltd., publishers of Thom's "Official Directory," are now preparing for publication an entirely new work, which they will also publish immediately, entitled "A Directory of the Manufacturers and Shippers of Ireland." There is in Ireland itself a strenuous and sustained movement for the promotion and development of the manufacturing industries of the country, and it is unquestionable that amongst Irishmen abroad, as well as in the United Kingdom, there is a generous desire to widen the markets for Irish products. The publishers have, we understand, secured the co-operation of Irish writers who are specially competent to contribute articles upon the economic conditions influencing the manufacturing industries and commerce of the country.

REVIEWS OF BOOKS.

MAY AND WORTH ON DISEASES OF THE EYE. (*a*)

THE popularity attained by former editions of May on Diseases of the Eye evidently induced the authors to produce a joint work, with the object of combining in one volume the best teaching of the American and British Schools of Ophthalmology. By so doing, without doubt they have succeeded in compiling a text-book on Diseases of the Eye which, as far as can be judged, should become one of the most popular on both sides of the Atlantic. It goes without saying, of course, that the joint work is a great improvement upon the last edition of May. For example, obviously no expense has been spared in the reproduction of wood-cuts, coloured drawings of the fundus, and of external diseases of the eye. Indeed, herein is the feature of the book; we know of no work of the kind in which so excellent and profuse a display of the pictorial art has been made use of. So far as the text is concerned, no detailed criticism is called for, in view of the popularity achieved by previous editions of "May." Suffice it, however, to say that we can confidently recommend the work as a trustworthy guide to diseases of the eye, being, as it is, up-to-date, sound, and practical. Practitioners, therefore, and students alike will find it precisely the kind of work which will meet all their requirements in this regard.

STUDIES IN BLOOD PRESSURE. (*b*)

THE information furnished by the investigation of blood pressure, or hæmomanometry, in diagnosis and prognosis, is gradually becoming more generally utilised As it is still in great measure *terra incognita* to many, Dr. Oliver's practical directions how to take the readings and his indications as to their clinical import will fulfil a want which, if not long felt, is none the less a want. The information is nominally conveyed in two lectures delivered in 1905 at the University of London, the only advantage of this literary form being that the author addresses his readers as "Gentlemen," and is enabled to make a much freer use of the first person singular than would otherwise be becoming. It is but quite recently that a portable instrument has been devised to measure the blood pressure, the importance whereof, empirically estimated by the touch, has long been recognised by physicians. At present quite a number of models are available, and the author pictures a modification of his own. This comports a supplementary pressure-bag for the wrist, the object of which is to provide a more trustworthy index of cessation of pulsation than the finger affords. Lecture I. deals with the technique of the investigation, Lecture II. being devoted to the clinical significance of variations in blood pressure. One of the first points is the unsuspected fallaciousness of digital estimates of arterial tension. The thermometer has its surprises, but they are trivial in comparison, hence the value of a method which enables us to obtain approximately trustworthy data even in inexperienced hands. As with other clinical data, however, the value of the observation lies in its application. It is more particularly in the domain of cardio-vascular disease that observations of blood pressure are of the greatest assistance, but to render the information of practical value the reader must study what the author has to say on this interesting subject.

RATIONAL VOICE PRODUCTION. (*a*)

VOICE production, like the art of the healer of the sick, would seem to engender quackery and charlatanism, and amidst the babel of contending "professors," the serious student and would-be pupil hesitates and is only too often lost in the toils of a "system" which ruins the little voice possessed, and deprives him of the means and opportunities for securing a sure path in what is the most glorious of pursuits. To all desiring guidance and warning, stimulus and scientific exposition whereby the fads and fancies of the extravagant, and the follies and worse of the ignorant may be detected, we commend this most artistic and yet highly reasonable handbook. Mdme. Carolo has done wisely to unite her very fascinating studies of the science and art of voice production to the necessarily somewhat prosaic although eminently practical descriptions of a medical observer. In this work Dr. Daniel deals with the Anatomy and Physiology of Singing, and explains its mechanism. The impediments to an effective use of the voice are described and the advantages and dangers, when improperly employed, of singing are explained in a manner simple and accurate. The most important sections of the work are written by Madame Carolo, with a grace and true artistic appreciation of diction, which, quite apart from the value of the opinions expressed, makes the work one of peculiar attractiveness and exceptional charm. The section dealing with the all-important question of production and control of motive power is a thoroughly scientific exposition on the science and art of "breathing," an all-essential matter on which but few have reliable knowledge. In the limited space at our disposal it is difficult to give any adequate idea of the rational presentation of the artistic suggestions and scientific foundations which are manifest throughout this work; suffice it to say that everyone interested in the development of the voice or desiring to enter into a full appreciation of "the divine gift," should study this remarkable volume. The book is also marked by originality in its illustrations, and in general get-up leaves nothing to be desired.

(*a*) "A Manual of Diseases of the Eye." By Charles H. May, M.D., New York, and Claud Worth, F.R.C.S.Eng. With 20 coloured plates and 315 other illustrations. London: Bailliere, Tindall and Cox. 1906. Price 10s. 6d.

(*b*) "Studies in Blood Pressure." By George Oliver, M.D., F.R.C.P. London: H. K. Lewis. 1906. Price 2s. 6d. net.

(*a*) "The Common Sense of Voice Development." By Irene San Carolo, R.A.M., A.R.C.M., and Patrick Daniel, D.P.H., L.M.S., L.R.C.P., M.R.C.S. Large crown 8vo. Pp. xii., 196. With 12 illustrations. London: Bailliere, Tindall and Cox, Price 5s. net.

MEDICAL NEWS IN BRIEF.

Election of Direct Representatives upon the General Medical Council.

By the time this list is in the hands of the profession, its members will have received the voting papers. It is not for us to urge the claims of any particular candidate, but our columns have been open to the addresses of all. We would, however, urge the importance of every vote being utilised at the present important juncture. The last day for the return of voting papers is December 7th; the declaration of the poll will be made on December 12th. The final list of the English candidates, arranged alphabetically, is:—G. H. Broadbent, M.R.C.S.Eng., L.R.C.S. and L.M.Irel.; G. Brown. M.R.C.S.Eng., L.S.A.; H. Langley Browne, M.D. Birm., F.R.C.S.Edin.; G. Jackson, F.R.C.S.Eng., L.R.C.P.Lond.; H. A. Latimer, M.D.Dun., M.R.C.S. Eng.; L. S. McManus, M.D., M.Ch.R.U.I.; J. Rutherford Morison, M.B.Edin., F.R.C.S.Eng.; C. J. Renshaw, M.D.St.And., M.R.C.S.Eng.; J. M. Rhodes, M.D.Brux., L.R.C.P., L.R.C.S.Edin.; F. J. Smith, M.B.Oxon., F.R.C.P.Lond., F.R.C.S.Eng.; and Joseph Smith, M.R.C.S.Eng., L.S.A. The Scotch candidates are Dr W. Bruce, M.D.Aberd., L.R.C.S. Edin., and Dr. N. Walker, M.D., F.R.C.P.Edin.

Dangerous Industries.

LAST week, in the Commons, Mr. Parker (Halifax), on behalf of Mr. Jowett (Bradford, W.), asked the Home Secretary whether he was aware that during the first nine months of the present year 483 cases of poisoning had occurred among workers in various industries, and whether he could promise early legislation with a view to dealing more effectively with the industries in which the cases occurred. Mr. Gladstone (Leeds, W.): Yes, I am aware of these statistics of poisoning cases for the current year which are compiled by my department. The Home Office has very full powers under the Factory Act of dealing with dangerous trades—in particular by the issue of regulations under Part IV. of the Act. That its action has been attended by a considerable measure of success is, I think, shown by the fact that the number of cases of poisoning has fallen from 1,331 in 1899 to 663 in 1905—a reduction of 50 per cent. in six years. Earlier in the session I laid on the table of the House a memorandum showing the action taken by the Home Office with regard to dangerous trades, to which I would refer the hon. member. Further codes of regulations are in preparation, among which I may mention a code for the horse-hair industries in connection with anthrax, and the revision of the existing codes for paints and colours and the enamelling of metals, which have been found to be inadequate. I may also mention that I am inquiring into the use of poisonous woods in certain manufactures. I do not think I can usefully propose further legislation on the subject at the present time, but, as the hon. member is aware, the Government are taking an important step, and one which I anticipate will have beneficial results, in bringing industrial poisoning within the scope of the Workmen's Compensation Bill.

The Leeds Nursing Scandal.—A Sensational Development.—An Arrest Followed by Suicide.

LAST week the case concerning a Leeds private "maternity home" has taken a sensational turn. On Monday the police arrested a man, aged 42, named Arthur Manson Craythorne, and charged him with using a surgical instrument for an illegal purpose. During the same night Craythorne put an end to his life, using, it is said, morphia for the purpose. The dead man, it appears, had been educated for the medical profession, but he never became a legally qualified practitioner. Up to five years ago he was dispenser and assistant to a well-known Leeds surgeon. Since then he has occupied a consulting-room in Pontefract Street, and set up a sort of irregular medical practice. His attractive personality drew around him many friends, and he was generally "hail fellow well met" amongst his acquaintances. But he never got through his examinations, and remained unqualified. He was married, but had no children.

Munificent Gifts to Medical Charities.

MR. H. L. BISCHOFFSCHEIM, in order to express his happiness on reaching his golden wedding, has given £100,000 to medical institutions of the metropolis:—Cancer Research Association, £40,000; the King's Hospital Fund, £10,000; the King's Sanatorium, £10,000; Charing Cross Hospital, £2,500; Great Ormond Street Children's Hospital, £2,500; London Hospital, £2,500; Middlesex Hospital, £2,500; Queen Charlotte Lying-in Hospital, £2,500; Metropolitan Provident Medical Association, £2,500; St. George's Hospital, £1,000; Surgical Aid Society, £1,000; Convalescent Homes Association, £1,000; Daneswood Sanatorium, £10,000; Tudor House Sanatorium, £6,000, etc.

Discovery in Yellow Fever.

A REUTER telegram has been received from the expedition of the Liverpool School of Tropical Medicine which has been in Brazil since the commencement of 1905 with the object of making research into yellow fever. It states that the expedition has just been successful in proving that chimpanzees can be infected with yellow fever by means of the Stegomyia mosquito. This discovery will be of the highest importance to those carrying out investigations into the disease Both the medical experts of the expedition contracted yellow fever in the earlier stages of their investigations.

Preservatives in Food.

A CONFERENCE, under the auspices of the Incorporated Institute of Hygiene, on "Preservatives in Food: their Use and Abuse," will take place tomorrow (Thursday). Professor Tunnicliffe, M.D., who was a prominent member of the Commission appointed by the Local Government Board to inquire into this subject in 1899, will preside.

The Anti-Opium Regulations.—Opinions in Shanghai.

THE native Press, says the *Times*, is curiously reticent on the subject of the new regulations for giving effect to the edict for the abolition of opium smoking The explanation given by the editors is that they prefer to await the issue of the further edict and proclamations necessary. The local foreign Press recognises the importance of these regulations, if only because they afford undeniable proof of the sincerity of the progressive party's desire for radical reform and their influence with the Central Government. Hearty sympathy is expressed with the action of the Throne in supporting measures which, if effectively enforced, must confer the greatest benefit on the nation, while the practical, businesslike wording of the regulations meets with general approval. At the same time the very vastness of the scheme compels a suspension of judgment, and induces doubt of the possibility by an act of legislation of compelling 150 millions of people to discontinue the opium habit. It is recognised that the practicability of this stupendous reform depends chiefly on the loyal co-operation and self-denial of the provincial officials, many of whom will be compelled to retire into private life, while others will be deprived of an important source of revenue.

Public opinion, native and foreign, strongly supports the anti-opium movement. Nevertheless the

vested interests of the yamens and the opium dealers will naturally be opposed to the reform. Finally, it is recognised that, if the regulations are hereafter compromised or abandoned owing to the Government's inability to enforce them, a severe check will have been inflicted on the progressive party in Peking—a consideration which must stimulate reactionary activity on this question. The urgency of the regulations and the early abolition of all opium divans creates a situation of remarkable interest.

The Hastings Libel Case.

ANDREW DUNN TURNER, surgeon, who pleaded guilty on the previous evening to publishing to Edward Thomas Burchatt Austin a letter containing divers false, scandalous, malicious and defamatory matters concerning the character of Kate Austin, his daughter, at Hastings, came up for sentence. Addressing his lordship on prisoner's behalf, Mr. Horton Smith said this man's life had been one of considerable pain, and the things which he said in the letter he had done were merely the imagination of a disordered mind. Years ago he received a very severe injury to his thigh, and had undergone no fewer than nine operations. He had been driven by the pain to take a large quantity of morphia, the effect of which was to cause not only physical, but moral and mental degeneration. Testimonials he had showed that from 1877 down to a recent date prisoner had stood high in his profession, and was of high moral character. The Salvation Army were prepared to receive the prisoner into a home.—Mr. Frank Septimus Barnett, M.R.C.S., speaking from a knowledge of prisoner for sixteen or seventeen years, said few men had suffered more actual pain over such a long period as prisoner.—His lordship said it was urged that prisoner had given way to taking morphia, but, as a doctor, he must have known the effect, and he was really in the same position as a person who, knowing that drink would be prejudicial to him, still indulged in it. The best thing he could do for prisoner was to keep him where he had been for the past four months—in prison, where every care would be taken of him. He would be sentenced to six months' imprisonment.

Society of Apothecaries of London.

AT the annual dinner of this Society, held a few days since, in the Hall of the Institution, the Master (Mr. E. Parker Young) presided, and among those present were Professor Clifford Allbutt, who, in submitting "The Society of Apothecaries of London," observed that in course of time the Royal Colleges of Physicians, and Surgeons, and the Society must unite into one great academy of medicine. The profession was suffering badly from the present divisions. They knew there were honourable men in its highest ranks who practised both medicine and surgery, and the distinction was a hollow one. The Master gave "The Royal Colleges of Physicians and Surgeons," and alluded to the society's work in advancing medical science and in keeping up the standard of their examinations. He remembered that it had about 10,000 Licentiates. Examining the statistics of the candidates appearing for examination for naval and military commissions last year, he found that the Licentiates of the Society stood first. They were trying, by a private Act, to alter their title, and the General Medical Council had very kindly offered no opposition. He thought that the public did not quite understand that they gave an examination in midwifery, medicine, and surgery. Mr. Henry Morris, President of the Royal College of Surgeons, replying for both institutions, said that the two Royal colleges were intimately associated with the origin and development of the Society. The differentiation of the profession into physicians, surgeons, and apothecaries, or general practitioners, was also associated with the origin and growth of the pharmacopœia and the establishment as a complete order of the pharmaceutical chemists and druggists. This differentiation of the profession afforded an excellent illustration of the way in which the dissensions, the jealousies, the ambitions, and the self-interest of different sections of society might be for the general good and the public profit, provided that there were behind high principles and worthy motives.

United Kingdom Hospitals Conference.

A conference of representatives of hospitals and others interested in the problem understood by the term "Hospital Abuse," will be held in the theatre of University College, London, on Thursday, December 6th, to co-operate with the members of the Hospitals Committee of the British Medical Association in revising and extending the proposals of a previous conference, and to express their opinion on the matters submitted. Over 150 hospitals have appointed representatives to take part in the forthcoming proceedings.

Fined for Non-Notification.

AT Dudley Police Court last week Dr. Maclure, of Brierley Hill, was fined 20s. and costs for failing to notify a case of puerperal fever to the medical officer of health. Dr. Maclure's defence was that he was not called in until the woman was in extremis, and when she died he reported it to the police.

Conviction under the Medical Act.

THE Stipendiary at Chatham has fined George Charles Smith £25 and costs for using the title of surgeon-dentist after his name had been struck off the Register of the British Dental Association. The magistrate said the defendant had been previously convicted at Lewisham, and the maximum penalty had been imposed to bring him to his senses, as he was deliberately flying in the face of the law. Defendant stated that the Association struck him off because he canvassed for business, and because he supplied artificial teeth on the deferred payment system.

Fire in a Bacteriological Laboratory.

On Sunday night an explosion occurred in the laboratory of the Mercy Hospital, Pittsburg. Many hundreds of tubes containing cultures of various pathogenic micro-organisms were smashed, and their contents were scattered far and wide. The inhabitants of the town were thrown into much alarm on learning of the accident, and extraordinary precautions are being taken to prevent the spread of any diseases that might possibly arise from the accident.

Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have received the L.S.A. Diploma of the Society, entitling them to practise medicine, surgery, and midwifery:—L. C. W. Brigstocke, F. G. Edholm, C. J. M. Lawrence, W. S. Mitchell, L. Nicholls, and J. W. Peatt.

Royal College of Surgeons, Ireland—Dental Examination.

The following candidates, having passed the necessary examination, have been admitted Fellows of the College:—A. Leventon, L.R.C.S.I., etc., Captain I.M.S.; W. L. Martin, L.R.C.S.I., etc., Surgeon R.N., and A. W. Tuke, M.R.C.S.Eng., Captain I.M.S. The following candidate passed the Primary Part of the examination: Mr. H. S. Meade.

THE following candidates having passed the necessary examination, have been admitted Licentiates in Dental Surgery of the College:—Mr. W. T. Anderson (Galway), Mr. P. M. Black (Dublin), Mr. R. F. Cooper (Wexford), Mr. J. E. Hogan (Dublin), Mr. P. D. McCreery (Kilkenny), Mr. A. K. Macdonald (Dublin), Mr. T. J. Ollivere (Cork).

Trinity College, Dublin.

THE following candidates passed the Final in Medicine, Michaelmas, 1906:—Thomas O. Graham (passed on high marks), Cecil T. Conynyham, John Gray, Percy B. Egan and Dudley F. Torrens (equal), Arthur E. Knapp, James E. McFarlane, Thomas B. W. MacQuaide.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

The Cardio-Vascular Lesions of Chorea.—Thayer (*Journal of the American Medical Association*, October 27, 1906), analyses the records of 808 cases of chorea, with special reference to the cardiac and vascular lesions discovered. He notes the frequency with which a history of rheumatism was obtained, in spite of the fact that rheumatism in children commonly runs a mild and atypical course. In 175 cases organic lesions of the heart were deemed probable; 111 of these were cases of mitral insufficiency, 7 of mitral stenosis, 39 of double mitral disease, 10 of mitral and aortic insufficiency, 1 of mitral stenosis and aortic insufficiency, 1 of double mitral disease and aortic insufficiency, and 6 of acute endocarditis, probably mitral in situation. Thayer finds, further, that cardiac involvement was more common in cases where there was a history of acute polyarthritis, and also in cases where there were frequent recurrences. R.

The Blood Pressure in General Paralysis.—Walton (*Journal of the American Medical Association*, October 27, 1906) sets himself to disprove the common notion that general paralysis is accompanied by a low blood pressure. His observations were made on 108 male patients, 64 of whom suffered from definite cardiac, renal, or arterial disease. He concludes:—(1) The average blood pressure in general paralysis is high; (2) this is due to the prevalence of atheroma, with its cardiac and renal accompaniments; (3) the average blood pressure in cases of general paralysis without arterial, cardiac, or renal disorder is probably lower than in health; (4) the test is not likely to be of any diagnostic value. R.

The Blood in Yellow Fever.—It has long been taught that in yellow fever the histological elements of the blood underwent complete dissolution, and that the blood as a whole became more fluid than normal, losing its coagulability. Modern investigation by Sternberg, Finlay, and others has shown the falsity of the first of these propositions. Marks (*American Journal of the Medical Sciences*, November, 1906) disproves the second. In the case of eight typical cases of yellow fever, he has tested the coagulability of the blood, with Wright's coagulameter. The minimum time occupied in coagulation was two minutes and forty-five seconds, the maximum four minutes and twenty seconds, the average three minutes and fifty-two seconds. From these results there can be no doubt that the coagulability of the blood is normal. R.

Hodgkins' Disease and Lympho-Sarcoma.—All who have studied the condition of the glands in Hodgkins' disease and in lympho-sarcoma have been struck by a remarkable similarity of structure, and during the past few years the view has been put forward that the diseases are of the same nature, differing, if at all, only in degrees of chronicity. Gibbons (*American Journal of the Medical Sciences*, November, 1906), from a study of nine cases of one or other disease, strongly supports this view. Six of the cases correspond in every way to the clinical and pathological type known as Hodgkins' disease, while the other three were of an undoubted malignant character, the disease affecting not only the lymphoid tissues, but infiltrating adjacent structures. The clinical picture in all the cases, however, was very similar, and the histological structure showed no point of distinction. The lymph-glands over the whole body were involved, and in those which came to the *post-mortem* table, five in number, metastases were found in the liver in four, in the spleen in four, in the kidney in two, in the lungs, the pericardium, and the pancreas, in one each; while in three of the cases the picture of malignant infiltration was complete, in the others, although the surrounding structures were intact, the capsule of the gland was infiltrated. Apart from the undoubted malignancy of some of his cases, Gibbons argues strongly that the histological structure is more suggestive of neoplasm than of infective granuloma. The irregularity of arrangement, the character of the fibrous stroma, the large number of mitotic figures, and the nature of the giant cells occasionally encountered, are points in favour, he thinks, of the disease being a form of sarcoma. R.

Further Studies in Syphilis.—Metchnikoff and Roux publish (*Annales de l'Institut Pasteur*, October 25, 1906) a further memoir dealing with their experimental researches on syphilis. (1) They relate certain experiments which go to show the possibility of attenuating the syphilitic virus by passage through animals. It was found that when a number of baboons were inoculated in series, the time required for symptoms to appear gradually grew shorter. Thus, in one series, from 19 days at the start, the periods diminished, till at the ninth passage only eight days were required. From this shortening of the period of incubation, one may assume a gradual heightening of the virulence toward the particular species employed. At the same time, however, there was a decreased virulence toward other species. Thus, a chimpanzee—the animal next to man most susceptible to syphilis—was inoculated with virus from a baboon at the eleventh passage without any sign of syphilis supervening; a baboon inoculated with the same virus showed typical lesions in nineteen days. Other chimpanzees, inoculated at the sixth and seventeenth passages, also remained free of the disease. In the human subject also, Metchnikoff and Roux believe to have observed syphilis of an attenuated virus. One of their laboratory attendants accidentally inoculated himself on the lip while caring for the animals used as subjects of experiment. The resulting ulcer did not clinically suggest syphilis; there was no glandular enlargement, and there were no later symptoms. Several apes, including three chimpanzees, were inoculated from the sore. The chimpanzees remained well, but several baboons of various species developed typical syphilitic lesions. One may conclude that the syphilis from which the attendant suffered was of attenuated virus not only to man but to the chimpanzee. Determined to put the point to further test, the investigators inoculated with syphilis at the fifth passage an old woman of 79, who submitted herself for experiment. At the same time, and with the same material, they inoculated a chimpanzee. Both subjects developed slight papules at the seat of inoculation, more marked in the ape, but neither showed any further sign of syphilis. From these various observations the authors conclude that there is a possibility of obtaining a vaccine for syphilis. In the absence of dead organisms, this can only be got by attenuating the living virus by passage. They suggest the advisability of submitting prostitutes at the beginning of their career to such vaccination. No harm can be done, they claim, since persons of this class are almost certain, if unprotected, to suffer from the disease eventually. In countries, too, like Russia, where extra-genital syphilis is rife, the question of vaccination as a general prophylactic measure might be discussed. (2) The authors discuss further, and defend against criticism, their views as to the possibility of preventing syphilis by the aid of calomel ointment. They hold that the failure of other observers to parallel their own success was due either to the use of too weak an ointment, or to allowing too long a period to elapse after infection before inunction was practised. They believe that the ointment should

contain from 25 to 33 per cent. of calomel, and that it should be applied within a few hours of infection. R.

Primary Cancer of the Ovary.—Miss McIlroy (*Journal of Obstetrics and Gynæcology of the British Empire*) publishes an important study of this condition, viewed from both the clinical and pathological standpoints. Among the conclusions are: (1) Most frequently both ovaries are affected, the one showing a more advanced condition than the other. (2) In the early stage the capsule is firm, being composed of fibrous tissue; later it becomes friable, and the tumour tissue forms surface proliferations. (3) Evidence of previous benign change in the ovary is usually to be found. (4) The epithelial cells are derived from the cells lining the follicles and from the cells derived from the germ epithelium. Karyokinesis is present. R.

Behaviour in the Body of Certain Organic and Inorganic Compounds of Phosphorus.—Dr. Tunnicliffe contributes a paper on this subject to the *International Archives of Therapy* for this year. After briefly reviewing the previous work that has been done on the subject, he sets himself three questions, which he has attempted to answer by observing the metabolic changes in two children to whom organic and inorganic phosphorus compounds were intermittently administered. The questions were—(1) Is it possible in the healthy human child to increase the amount of phosphorus retained in the body by increasing the phosphorus of the diet; (2) how do organic and inorganic phosphorus compounds compare in value as sources of phosphorus to the body; (3) what is the effect of phosphorus compounds on proteid assimilation. The conclusions that he has arrived at are important, and are stated as follows:—(1) In the healthy child the addition of an organic phosphorus compound to the diet is followed by an increase in the amount of phosphorus assimilated by and retained in the body; (2) the exhibition of an organic phosphorus compound increases the amount of the nitrogen of the food assimilated; (3) inorganic phosphorus compounds exert no favourable influence on nitrogenous assimilation, nor do they lead to an increase of prosphorus retention; (4) the phosphorus contained in the sodium glycero-phosphate of casein is practically entirely assimilated by the body. M.

Sahli's Desmoid Reaction.—A paper on this subject is contributed by Dr. Boggs to the *Johns Hopkins Bulletin* for September, 1906. The test, as is well known, is employed for the purpose of discovering the digestive power of the gastric juice, and consists of the following:—A pill is made out of a grain of methylene blue and a little liquorice powder, and is wrapped up in a rubber sack, the neck of which is tied by three turns of oo catgut; this is administered to the patient, and the time when the urine becomes blue is noted. As catgut can only be digested by the acid gastric juice, and is unaffected by trypsin and other intestinal enzymes, the time of appearance of the reaction indicates the activity of gastric digestion. The time of appearance may vary from five to twenty hours. The writer has examined 34 patients suffering from gastric symptoms, and has compared his results with results obtained by chemical analysis of the gastric juice in the same cases. His conclusion is that the method is valuable and reliable. In seven cases of stomach cancer the test was entirely negative in six, and the result doubtful in the seventh; and in seven cases of pernicious anæmia it was also negative. In all of these fourteen cases the chemical analysis showed the absence of hydrochloric acid; also in every case that HCl was found by analysis the desmoid test was also positive. He regards Sahli's test, however, as more delicate than the analytic test, as the pill, being heavy, remains in the stomach for the maximum time, and so tests fully the gastric digestive powers. M.

Aneurism of the Splenic Artery.—A case of this rare condition is reported by Dr. Reynolds (*South African Medical Record*, September, 1906). The patient was a female, æt. 28, who complained of pain in the back to the left of the middle line, and of flatulence. There was no history of syphilis, and no physical signs could be detected. Death occurred suddenly while the patient was in bed. At the autopsy the spleen was found much enlarged, and an aneurism was present on the splenic artery. This was about two and a half inches in diameter, was half filled with decolourised clot, and presented a ragged opening through which a finger could be passed. Rupture had taken place into the peritoneal cavity, which was full of blood. The author points out that only about twenty case in all of splenic aneurism have been recorded, and that it has almost invariably been unsuspected during life. M.

The Pathology of Chorea.—Drs. Poynton and Gordon Holmes record the result of their recent investigations into the etiology and pathology of chorea (*Lancet*, October 13, 1906). Their report is founded on the examination of the brains of three fatal cases of the disease. In each of the cases they found great hyperæmia of the brain cortex and of the meninges, and in many cases thrombosed vessels. Patches of necrosis were also found, and a very constant feature was perivascular small round celled infiltration and serous exudation. Many nerve cells presented chromatolysis. In all of the cases also diplococci were found in the vessels of the meninges and in the walls of some of the blood-vessels within the substance of the brain. Similar organisms were obtained in one case from the heart valves in pure culture, and were found to produce multiple arthritis and pericarditis when injected into animals. The authors, as a result of their findings, conclude that chorea is not a complication but a result of the rheumatic process, and that the symptoms are produced by the action of a toxin on the nerve cells—the toxin itself being the product of the diplococcus rheumaticus, which organism they believe to be identical with that they have observed in the brain in choreic cases. M.

Blastomycosis of the Skin.—Primrose describes a case of this rare pathological affection (*Edin. Medical Journal*, September, 1906). The disease occurred in a man, æt. 28, and took the form of multiple skin tumours, fourteen distinct lesions in all being present. One patch on the upper lip resembled closely an epithelioma. It was about an inch in transverse and vertical diameters, and was raised considerably above the surface. It presented a warty appearance of a dirty yellowish colour, with here and there some hæmorrhagic spots; the base was not indurated, and the growth stopped quite abruptly, the surrounding tissues being apparently quite healthy. Similar lesions were present on the cheeks, at inner canthus of the eye, on the trunk, and on the extremities. Scrapings made from the patches and teased out in liquor potassæ revealed blastomycetes in the form of round, highly refractile, double-contoured bodies; while sections made of an excised portion showed epithelial hyperplasia, hyperæmia, leucocytic infiltration, and small abscesses. In the neighbourhood of the abscesses there were patches of granulation tissue containing giant cells and epithelioid cells. Under treatment the tumours rapidly improved. M.

Leprosy in Buenos Ayres.

AT the fifth sitting of the conference on leprosy, today, Dr. Sommer and Dr. Aberastain stated that leprosy was obviously increasing in Buenos Ayres, and that rigorous measures must be taken.

IT is announced that the fifth periodical Congress of Gynæcology, Obstetrics, and Pædiatrics, will be held at Algiers, April 1st to 8th, 1907, under the general presidency of Professor Queirel, of Marseilles, who will also preside over the Section of Obstetrics. Dr. Boursier, of Bordeaux, will be President of the Gynæcological Section, and Dr. Guinon, of Paris, of that of Pædiatrics. The General Secretary is Professor Jules Rouvier, 52, Rue Daguerre, Algiers, to whom all communications should be addressed.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

TAN.—It is yellow phosphorus, also known as white phosphorus, which is the chief cause of industrial phosphorus poisoning. But the trichloride is used in small quantities in some manufactories. The sesqui-sulphide can be, and now is, largely used in match-making.

MR. W. W. RUTHERFORD, M.P., AND THE HERBALISTS.

THE *Liverpool Daily Courier* is responsible for the following extraordinary statements by an English member of Parliament regarding the suggested Government recognition of the herbalists as a professional body. It is difficult to realise how any man occupying so responsible a position could have committed himself to the attitude revealed in his answer to a Mr. Cowie, giving an account of his successful treatment of cancer with violet leaves! The *Courier* reports Mr. Rutherford as writing:—"What I think will eventually happen is that a general Bill will be brought in enabling all such professions and businesses to be registered as a sort of Incorporated Society; and I confess, for one, that, having regard to the considerable number of herbalists who are reasonably qualified to carry on their business, and having regard also to a number of other people who set up as such, and who are not so qualified, it would be exceedingly desirable that the properly qualified body should be recognised as one of the societies which would come within purview of such a Bill."

RETRACTOR.—The poison you speak of—tyrotoxicon—is a rare one in cheese. Probably poisonous cheese is due to micro-organisms. Some bacilli resembling in some respects B. coli communis have been found by different observers.

OPSONIN.—The suggestion is a good one and you might submit it to your colleagues in the neighbourhood—say by resolution at your medical society. If opinion is decided on the point, we should be glad to hear.

TABLOIDS v. TABLONES.

IN our issue for the 14th inst. we referred to a case just decided in the High Court, in which Messrs. Burroughs, Wellcome and Co. sued the Capsuloid Company, Limited, for an infringement of their brand "Tabloids" by the newly-coined word "Tablones." By a slip of the pen we referred to the infringement as "Capsuloids," whereas that complained of by Messrs. Burroughs, Wellcome and Co. was "Tablones," by the Capsuloid Company. Our attention having been called to the slip, we are glad to make the necessary correction.

DR. McV.—We thank you for the cutting, which is most interesting. As, however, the circumstances alluded to in the article have not fully come under our notice, we cannot comment on them clearly. It is refreshing to have appreciative reference in the lay press after so much that one sees.

GLOXIENSIS AND CORASSA.

A CORRESPONDENT asks what was the sequel of this case, to which we referred three weeks ago. The case came on at the Sussex Assizes on Monday last, and ended with a sentence of three months' hard labour for obtaining money by fraud. The quack, it may be remembered, advertised from Brighton some marvellous powders under the above descriptions, which would cure everything to which "flesh is heir." He was doing a big trade as Dr. Hawkins, M.D. U.S.A., when the police inconsiderately intervened, took possession of his person and the precious powders, and for their pains have now the trouble of looking after him for the next three months.

DR. H. J.—The question was answered in this column last week.

AN INTERESTED CONTRIBUTOR.—The question is under consideration.

F. H. T.—The combination of the two names is curious, and we trust genuine. One cannot forget that any combination is possible. There are even two Winston Churchills. It is possible to take steps only if the name has been adopted obviously for fraudulent purposes.

► DR. S. T.—Stricture of the urethra in women is, as you say, rare, but a certain amount of narrowing is not so very uncommon. As in the male, gonorrhœa is the chief cause.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, NOVEMBER 28th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.)—8.30 p.m.: Pathological Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. P. J. Freyer: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. J. Fawcett: Some Pathological Specimens with Interesting Clinical Histories.

THURSDAY, NOVEMBER 29th.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—9 p.m.: Hughlings Jackson Lecture:—Sir Victor Horsley: The Illustration by Recent Research of Dr. Hughlings Jackson's Views on the Functions of the Cerebellum.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. Carless: Some Injuries about the Elbow-joint.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Coccus Diseases: I., Impetigo Contagiosa; II., Furuncle; III., Carbuncle; IV., Coccogenic Sycosis.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Mount Vernon Hospital, Hampstead).—5 p.m.: Demonstration: Dr. J. E. Squire: Cases of Chest Disease.

FRIDAY, NOVEMBER 30th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Mr. E. Clarke. Clinique. (Eye.)

Vacancies.

Royal Hospital for Incurables, Donnybrook, Dublin.—Resident Medical Officer. Salary £120 per annum, with board, &c. Immediate application to J. J. Thompson, Registrar. (See advt.)

Bristol General Hospital.—Senior House Surgeon. Salary £150 per annum, with board, residence, &c., in the house. Applications to the Secretary.

Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher Hall, Secretary.

Stretton House Private Asylum.—Indoor Assistant Medical Officer. Salary £150 per annum. Applications to Dr. Barnett, Stretton House, Church Stretton. (See advt.)

Bridge of Weir Consumption Sanatoria.—Assistant Resident Medical Officer. Salary £100 per annum, all found. Applications to R. Lockhart Bryden, Hon. Secy., 102 Bath Street, Glasgow.

Leeds University Faculty of Medicine.—Demonstrator of Bacteriology. Salary £200 per annum. Applications to the Registrar of the University.

County Asylum, Prestwich, Manchester.—Junior Assistant Medical Officer. Salary 150 per annum, with board, furnished apartments and washing. Applications to the Medical Superintendent.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary £150, with board, apartments, attendance, and washing. Applications to the Medical Superintendent.

Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to the Chairman of the House Committee.

Blackburn County Borough.—Education Committee.—Assistant to the Medical Officer of Health. Salary £150 per annum. Applications to Alexander Gow, Director, Education Offices, Library Street, Blackburn.

Appointments.

FLEMING, R. J., M.B., B.S.Durh., District Medical Officer by the Devonport Board of Guardians.

FORSYTH, CHARLES E. P., M.B.Aberd., Assistant Pathologist in the London School of Clinical Medicine, Seamen's Hospital ("Dreadnought"), Greenwich, S.E.

FULLAM, W. F., L.R.C.S.Irel., L.A.H.Dub., Certifying Surgeon under the Factory and Workshop Act for the Balbriggan District of the county of Dublin.

MORRICE, G. G., M.D.Cantab., M.R.C.P.Lond., Consulting Physician to the Royal Dispensary, Portland.

PATTERSON, NORMAN, M.B., B.Ch.Edin., F.R.C.S.Eng., Senior Clinical Assistant to the Golden Square Throat Hospital.

WADIE, M.D., M.R.C.S., L.R.C.P.Lond., House Surgeon to St. Peter's Hospital for Stone, London, W.C.

WEAR, ALGERNON, M.D., B.S.Durh., Honorary Medical Officer in Charge of Medical Cases at the Southern Branch of the Leeds Public Infirmary.

WHITFIELD, ARTHUR, M.D.Lond., F.R.C.P.Lond., M.R.C.S., Professor of Dermatology at King's College, London.

Birth.

BULLOCK.—On Nov. 22nd, at 26, Cyril Mansions, Battersea Park, Marian T. Bullock, M.B. Lond., wife of W. Carey Bullock, of a daughter.

Marriage.

TUNSTALL—SILBERSCHMIDT.—On Nov. 10th, at Holy Trinity, Sydenham Park, Alfred Croudson Tunstall, M.D., F.R.C.S. Edin., of S. Hackney, to Florence Adeline, eldest daughter of Moritz S. N. and Adeline S. E. N. Silberschmidt, of Rothay House, Sydenham.

Deaths.

GUTHRIE.—On Nov. 23rd, at 35, Briardale Gardens, London. Jessie Rose Black, widow of John Guthrie, M.D., of Brechin, N.B., in her 77th year.

SPAIGHT.—On Nov. 22nd, at Swiss Cottage, Dundrum, Co. Dublin, Alice Maude, widow of the late Robert Spaight, J.P., Affock, Tulla, Co. Clare, and daughter of the late James Molony, F.R.C.S.I., Clonmore, Tulla.

SYMES THOMPSON.—On Nov. 24th, at 33, Cavendish Square, London, Edmund Symes Thompson, M.D., F.R.C.P., aged 69.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, DECEMBER 5, 1906. No. 23

NOTES AND COMMENTS.

C.B. and the R.C.S.

THE persistent *hauteur* with which the Fellows of the Royal College of Surgeons regard the claims of the members to a voice in the government of the College is sufficient evidence of the cynical indifference of this corporation to the needs of the profession. The Fellows are, roughly speaking, consultants, and the members general practitioners. The Fellows elect the Council, control the College, appoint themselves examiners, and send a representative to the General Medical Council to see their "rights" are not infringed; the members, after paying very substantial fees for examination, are allowed to go into the world and fend for themselves. The College is not for them, and takes no further interest in them unless they misconduct themselves. The position is intolerable to all who realise the struggle of the general practitioner against outside odds, and that he should be wounded in the house of his friend is a bitter comment on the generosity of the more highly placed members of the profession. One cannot be over sanguine of Government interference, but we note with pleasure the courageous action of Sir William Collins and Mr. R. J. Price in personally laying the position before the Prime Minister. Sir Henry Campbell-Bannerman received them sympathetically, and said that he would look into the matter. More than this, perhaps, could not be expected, and it is difficult to see how the Government can take action. We hope, however, that there may be machinery which we know not of, and which may be set in motion as the result of the deputation.

Increased Clinical Instruction.

THERE is no doubt that increased clinical instruction in certain subjects is not only desirable, but is a necessity. Amongst such subjects, obstetrics, gynæcology, and diseases of children stand out prominently. It is absurd to think that a newly qualified medical man can successfully practise obstetrics on the amount of clinical teaching which is at present considered sufficient for him, and yet obstetrics is the very subject in which he stands in need of careful training. It is therefore satisfactory to learn that at the meeting of the General Medical Council referred to elsewhere, which rejected Sir Thomas Myles' motion to make students' lectures non-compulsory, it was resolved, on the motion of Mr. Young, "That it be remitted to the Students' Practical Midwifery Committee to consider and report as to the inclusion of clinical and practical work in the qualifying examination in midwifery and gynæcology." If it could be clearly proved the student had not time in the present crowded state of his curriculum to take up also such clinical and practical work, it would be a strong argument in favour of Sir Thomas Myles' proposal. Unfortunately, however, midwifery is the very subject in which it would be impossible to abolish systematic lectures, whose value, here at least, has been fully admitted. If surgical teachers have doubts as to the value of systematic lectures in surgery, would they be willing to see them abolished in order that the student should receive fuller practical instruction in midwifery and gynæcology?

Apothecaries' Act.

IT is one of the queer survivals of ancient practice that the Apothecaries' Society, though empowered to grant licences to practise medicine and surgery, are not able to call their licentiates physicians, surgeons, or doctors. Consequently the uninstructed public cannot distinguish the practitioner of medicine from the dispenser of physic, the term "apothecary" having from time immemorial been associated in their minds with a pharmaceutical chemist. As a matter of fact, the legal decisions with regard to the proper description of an L.S.A. are conflicting, but judges have recognised it as a hardship that a legally qualified practitioner in medicine or surgery cannot adopt the style which describes him to the public as such. We are not surprised, then, that the Apothecaries' Society intend to apply next session for an Act to empower them so to describe their licentiates that people may know them for what they are; the only opposition we can think of would come from those who might be inclined to think that such a step would postpone the "one-portal" system.

The Only Portal.

THE one-portal is bound to come sooner or later, and is sure to be strongly opposed by those corporations, such as the Royal Colleges, which draw the bulk of their income from examining, and regard their charters as conferring on them privileges for which they need make no return to the public or their diplomates. But it is only rational that the register should show what it is intended to show, namely, that all medical men have attained a certain substantial standard of knowledge, and not that they find their place on it by virtue of the approval of a body which trades in examinations. It is an absurd anomaly that a man may pass qualifying examinations and yet not be able to call himself "doctor," the one term whereby the public recognise the medical practitioner from the quack. "Registered Medical Practitioner" is about as useful an asset in practice as "Registered at Stationers' Hall" would be.

LEADING ARTICLES.

THE GENERAL MEDICAL COUNCIL.

THE General Medical Council have held their winter session, and from the President's address at the outset it was clear that the policy of marking time was to be pursued, probably because of the election in progress. As to that election, it may safely be said that it shows signs of being more keenly contested than any that has yet taken place, and we trust that it will be found that no practitioner has failed to register his vote. One of the arguments that is used with great unction by the opponents of increased direct representation is that medical men show so little interest in present elections that it would be folly to give more power into their hands. We do not agree with this conclusion, but we hold strongly that any man who fails to register his vote shows a want of loyalty to professional ideals that is highly blameworthy. If a man is not satisfied with things as they are, he cannot blame anyone but himself if he fails to use his vote; and if a man is satisfied, then the call to vote is even greater, for he has a multitude of professional brethren to whom the conditions of life are terribly hard and unfair. Only direct representatives have shown themselves in deadly earnest about the reform of medical grievances, the excellent people who are deputed to represent corporations and universities regarding such matters as questions of academic interest, quite subordinate in importance to the teaching of biology and the sanctioning of places where instruction in chemistry may be given. The Council needs good, hard-headed direct representatives; it needs men of position and integrity; but, above all, it needs fighters who can infuse into its august proceedings that spirit of enthusiasm which takes no count of difficulties. The direct representatives are the Labour party of medical politics, and, without dwelling on the special merits or demerits of Parliamentary issues, it is agreed on all hands that the Labour men in the House of Commons, though few in number, have made themselves an irresistible force. They have won this position by doggedness, determination, diligence, knowledge of what they want, and downright earnestness. Those are the qualities which we look for in direct representatives in the General Medical Council, and they will more than ever be needed now that Sir Victor Horsley has retired. The atmosphere of the Council is as serene as that of the House of Lords, and courage of no mean order is required to electrify it. We believe that this election is showing, and will show still further, that the general practitioner has bestirred himself, and that he expects from his representatives that unwearied forcing forward of pressing questions, and that discriminating forcing back of insignificant ones, which will lead to substantial reform. Looking through the agenda of this session of the General Medical Council, one would imagine that everything was for the best in the best of all possible worlds. A few trifling questions of the medical courses of study in Japan and Nova Scotia, some points about the teaching of midwifery, and minor alterations in the inspection of examinations formed, with the usual penal cases, the bulk of a bill of fare as jejune and unsatisfying as one could wish. We may, however, congratulate the General Medical Council on having successfully opposed the granting of charters to the British Optical Association and to the National Association of Medical Herbalists of Great Britain, Limited. The fight against the former is likely, we fear, to be a Pyrrhic victory ardently followed up, for the Association are seeking to turn the flank of medical opposition by means of a Bill in Parliament, which has powerful backing. This Bill must be carefully watched and vigorously met in every stage of its career, for it seeks to go back, as the Medicines Act has already gone back, on the principle of the Medical Act of 1886, when the one and indivisible nature of medicine, surgery, and midwifery was recognised by the Legislature. That position, it was hoped at the time, had been established for ever as the foundation of all progressive medical legislation. In spite, however, of the set-back received when the Midwives Bill passed in its final shape, it must never be conceded that it is possible for proper treatment of such persons to be undertaken by other than those trained in the three fundamental branches of medical science and practice. The Herbalists' Charter, as we have said before, hardly savoured of the serious; it was such manifest "cheek" for a body of worm-curers or weed-sellers to claim medical powers of any kind. These victories, important enough in themselves, can hardly be regarded as heroic, and they represent substantially all that the Council has achieved in the support of medical interests in what we may term its external relations. The President had to announce that, "acting on advice that it could not disregard," the Executive Committee had decided not to submit to Parliament the Bills they had prepared to remedy existing abuses. Well, there are always advisers ready to suggest delay, caution, and prudence; the profession want men who are ready to hit, to hit hard, and to take risks. It wants men prepared to tell the Council that it is badly constituted, that it does not represent the feelings of the medical profession, and that it must begin reform by letting Parliament know that it cannot do effective work till it is purged itself. We do not deny that the work of the Council has been uphill and that it has had to make its own position in the officially-recognised world, but its path would have been easier if it had had the whole-hearted support of its nominal constituents. One day the Council will awake to the fact that the profession is one of the most influential bodies in the community; that the practitioner of medicine is the friend and adviser of every household; and that if the machinery were put into working order public support of the medical view could be obtained in every nook and cranny in the land.

NOTES ON CURRENT TOPICS.

A Doctor's Dilemma.

As a leading dramatist Mr. G. Bernard Shaw well deserves the epithets of brilliant, witty, and original. His latest effort deals with the medical profession much on the lines of Molière. In a good-natured way he brings together on the stage a bevy of medical men, whom he endows with various grotesque foibles which suggest those of actual

living types to the found any day in the neighbourhood of Harley Street. Medical men will recognise the kind of specialist who believes in the removal of the "nuciform sac" for the relief or cure of every human malady. They will also recall poor and sometimes able practitioners in mean streets who have been fellow students of Court physicians and titled leaders of the profession. What they will not recognise, however, is Mr. Shaw's absurd travesty of the opsonic index. As a burlesque writer Mr. Shaw has to cast his net with an exceedingly wide sweep, but surely never dramatist landed a queerer fish than in this instance. As a matter of fact, to grasp the intricacies of the opsonic index demands a wide and highly technical scientific knowledge, and in its present form it is neither understood by one medical practitioner in a hundred nor applied by one in a thousand. When a non-medical dramatist, therefore, fixes on the opsonic index as the key to his plot he is likely to get into difficulties. To cut a long story short, a newly knighted physician, Sir Colenso Ridgeon, can treat only a limited number of patients in his clinic. He is persuaded by a lady to give the preference to her supposed husband, a clever, artistic scamp. The dramatic situation here presented is intense—but it is none the less impossible—and we venture to question its admissibility in any rigid scheme of dramatic art as the motif of a drama. Comedy writers, however, assume a good deal of licence in that and other directions, but if we ourselves stray into the fields of dramatic criticism we are likely to fall into morasses more entangling than those which are so boldly confronted by our versatile dramatist. His motto, indeed, might aptly be the sentence put by one of the greatest writers of his age into the mouth of one of his characters, "*Homo sum, humani nihil a me alienum puto.*" The latter part of the play somewhat loses its hold upon the audience, but we should advise all medical men, if possible, to make a point of seeing this extremely clever and humorous skit upon their own profession.

A Penal Case.

One of the penal cases before the General Medical Council last week was that of a Dr. H. C. Juler, who was summoned to appear and answer a charge that in July last he had been convicted of an act in violation of public decency in Hyde Park. We know nothing of Dr. Juler or of the details of the case, but his record shows him to be a well-qualified man. He is an M.D. of Aberdeen, an M.R.C.S. and L.M., England, and an L.S.A. of London. But as Dr. Juler was qualified in 1853, he must now be over seventy, and probably nearly eighty. Now, is it likely that a man who has passed an outwardly blameless life and attained this advanced age would suddenly commit the act of a guttersnipe without the operation of some pathological cause? These cases are unsavoury at the best, but medical men are well aware that old gentlemen not infrequently commit acts of an indecent character when they are the subjects of senile mental decay or of local troubles of the urinary organs, and it is neither rational nor merciful to regard them as other than the victims of morbid manifestations. Medical men strive to get courts of justice to take a scientific view of persons thus afflicted, sometimes successfully, but often unsuccessfully; but we do expect that a court of medical men will view them in the proper light, and treat them as subjects for medical care and not for penal discipline. The Medical Press and Circular always stands for the highest code of conduct among medical men, but as the Council did not have Dr. Juler before them we fear that a cruel wrong may have been committed.

The passing of Systematic Lectures in Medical Subjects.

Some years ago, when a Joint Committee of the Royal Colleges in Ireland was considering proposed alterations and reforms in their curriculum, a proposal was brought forward by the representatives of the Royal College of Surgeons that systematic lectures in medical and surgical subjects should be abolished and their place taken by more careful and extended clinical teaching. We believe that eventually the Committee approved of the proposal so far as it affected those subjects for which the College of Surgeons was responsible, but that when the Committee's report went back to the College, the Council disapproved of that portion of it. Since then the matter remained in abeyance, so far as any definite action was concerned, until the present meeting of the General Medical Council, when Sir Thomas Myles, the representative of the Royal College of Surgeons of Ireland, brought forward a motion to the effect that it should be remitted to the Education Committee "to consider and report how far it might be possible to dispense with the customary attendance of students on systematic lectures in the medical schools." A keen and interesting debate followed, with the result that seven members voted for the motion, and seventeen against it, while five members declined to vote, and four were absent. This result is very much what one would expect. A proposal of so revolutionary a nature, even if it is admitted to be desirable, could scarcely expect a greater measure of support on its first enunciation. There is no doubt that the more clinical teaching and the more practical work a student can receive and can perform during his course the better, but we are inclined to doubt if the existing opportunities for such teaching and work are sufficient to occupy the student's time. We doubt if the addition of the fifth year of medical study, in which a student was supposed to be free from the trammels of lectures and to devote his time entirely to practical work, has accomplished the wishes of its originators.

Mixed Boarding Schools.

There are a considerable number of people who think that the advantages of co-education outweigh the disadvantages which are apparent in the system. The mingling of the sexes, it is contended, tends to soften and render chivalrous the rough, uncouth nature of the young male, and to steel the shrinking female nature against the timidity by which it is beset. So far these enthusiasts have not made much progress in this country, and it is doubtful if they will. We are at one with them in condemning the vices which are too prevalent at public schools, but the obvious remedy, namely

vigilant and prescient administration, is seldom tried. The pride of the English public school system is the neglect of masters to look after the boys during their spare time, the boast being that youngsters thereby attain to early independence of character. That blessing is a doubtful one, and it is doubtfully achieved. Independence is a fine characteristic, but independence of moral and social laws, if cheaply bought, is heavily paid for afterwards. But we hardly fancy that the introduction of young girls into public schools is likely either to diminish vice or to transform boy nature. Indeed, we did not know that co-educationists intended more than that children of the two sexes should meet at day-schools, but the Rev. Cecil Grant has lately been appointed headmaster of a school at Harpenden where girls and boys are both to reside and be educated. Mr. Grant has many backers among headmasters and headmistresses, and we shall watch his venture with interest. Perhaps in the near future we shall have mixed teams of young "Springboks" ready to contest the honour of the old country.

Medical Inspection of School Children.

While the Education Bill is in the melting-pot no one can predict in what form it will eventually pass into law, or what shape its provisions may take. The only unopposed clause was that providing for the medical inspection of school children, and medical men may sincerely congratulate themselves that their teaching on this subject has so thoroughly permeated the classes and masses that all parties are agreed as to its necessity. But it must be confessed that there may be rocks ahead if the clause is made compulsory; after one or two changes, it now stands that local authorities *shall* make inspections, and though all looks fair at present, there is little doubt that in the future there will be squalls when the clause comes to be administered. In Dunfermline, where the Carnegie Trust provided, among other good things, a medical man to look after the physique of the school children, there has been objection on the part of a good many parents, and though the opposition is now disappearing it shows that the parents of British children are ticklish people to deal with. It would be a thousand pities if the compulsory nature of the examinations put up the backs of any body of people and tended to create opposition to this beneficent work. We believe that the value of medical care and inspection will soon be apparent to all, and will make itself popular on its own merits, but it is probable there would be more political sagacity in making the examinations permissive than in making them compulsory. Medical men wish to be recognised as the parents' friendly advisers, not as their official inspectors.

Food Preservatives.

On November 29th a conference was held in the Lecture Hall of the Incorporated Institute of Hygiene to consider the subject of preservatives in food, their use and abuse. The meeting was held at an opportune moment, for it is perhaps too much the fashion to imagine there is only one side to the question. There are many reasons that make it imperative to use preservatives in the transit and storage of some kinds of food. Alcohol and sugar, used for the purpose, so long as consumed in reasonable quantities, are a source of energy in the body and must therefore be regarded as foods. Salt is normally present in the body, but whether its presence in quantity is harmless may well be questioned. These and many other interesting points were discussed by the president, Professor Tunnicliffe, who remarked he would dread to think what would happen if they prohibited the use of saltpetre, which was neither a normal constituent of the body nor a source of bodily energy. He also alluded to the chemical preservatives such as salicylic acid, formic aldehyde, and so on. Professor Thresh claimed that public regulations should be made forthwith as to what preservatives might be used, with full details as to notification, amount and other particulars. A most interesting discussion followed on this highly important and practical subject.

The Brighton "Powder Case" Sentence.

The verdict in the notorious Brighton quack medicine vending frauds is calculated to astound the plain man who asks for equal justice all round. Here was a man, posing under various aliases as a clergyman, and carrying on a huge trade in worthless nostrums. He cheerfully undertook to cure any disease under the sun, and treated all applicants alike with powders composed of bromide of potassium and bicarbonate of soda. This physic, costing a few pence, was sold at extortionate prices to customers. The trade of this scoundrel, therefore, was nothing short of a cool, calculated, wicked and injurious fraud. He had carried on a huge advertising business for years, and must have amassed enormous profits. Yet the result of the trial is that the father was sentenced to three months' hard labour, while a similar charge against his son was withdrawn. At every Sessions and Assize Court in the Kingdom prisoners are sentenced to years and years of imprisonment for far less serious offences. The learned judge congratulated the Crown on their recent policy of undertaking prosecutions of the sort. After this exposure it is clear that any newspaper receiving advertisements in future from this scoundrel will be incurring a grave responsibility, and technically will probably become in the eyes of the law *particeps criminis*.

Slate Quarrymen and Cardiac Dilatation.

THE question of trade diseases is obviously one of importance to the community. Of late years there has been a growing tendency on the part of the State to inquire into, and, so far as possible, to limit the margin of industrial wastage from that cause. Fortunately, medical science has, of late years, made vast strides in the pathology of this wide and varied group of maladies. In not a few instances, however, our knowledge is scanty and inadequate, while in other directions it seems likely that sources of mischief are still unsuspected. An old and valued correspondent draws attention to a discussion upon cardiac dilatation due to working in slate quarries, a subject that was first noticed in THE MEDICAL PRESS AND CIRCULAR in June last. He has been

requested by Mr. Herbert Samuel to give evidence before the Committee of the Commons appointed to enquire into and report upon disease of an industrial origin, as apart from accidents. Having had some experience of Parliamentary Commissions, he has for the present declined to come up to London to give evidence. The subject, however, is of great medical interest, and we trust that he may be induced to bring it prominently before the profession through the medium of our columns. There must be many Welsh practitioners capable of throwing a deal of valuable light upon the question, and it need hardly be said that any communication of the kind would command a good deal of attention at the present moment, when the unsettled conditions of the Workmen's Compensation Act are so prominently before the public.

Pouring Cold Water on the Bath.

"Are we too clean?" is a subject that might be suggested for profitless discussion in the columns of our lay contemporaries when hard up for a sensation. It might even be used as an additional argument against the Soap Trust, and no stick is too bad to beat a dog with. The anti-soap party, however, would find a powerful ally in a Dr. Cerboni, who has lately been making strong remarks about the folly of washing. This gentleman, who has reached the ripe age of seventy-five and has never had a bath in his life, is filled with contempt for the insensate practice of keeping the skin clean. "To wash," he says, "is a proceeding repugnant to nature and injurious to health." Regular washing in his opinion exposes the body to cold, reduces the vitality, brings on premature death, and makes the skin dry, harsh, and brittle. Dr. Cerboni argues that by not washing the skin soon acquires for itself a "comfortable, natural deposit," which not only allows the skin to perform its natural function of secretion without let or hindrance, but also provides a culture-medium wherein beneficent germs breed and render harmless the attacks of pathogenic ones. Now a medical man who has reached the mature age attained by Dr. Cerboni can speak from experience if not with authority, and if he has faithfully followed the precepts he enunciates, there can be little doubt that he will make certain converts. But the climate, or the circumstances, or both, in Great Britain are different from those of Italy, and we hardly imagine that he will attract many followers in this country, outside the boundaries of "little Italy." Health or no health, the Britisher likes his tub, and it is an opinion, or perhaps a delusion, prevalent over here, that he is all the better for it.

Pharmacists for the Army.

Surgeon-General Evatt, with characteristic energy, is pursuing his campaign in favour of the appointment of expert pharmacists to the Army for service in time of war. There is no doubt that it is of importance to the efficiency of the soldier that the medicines ordered by the medical officer should be supplied as ordered, and if there is at present no guarantee of this, then the matter ought speedily to be set right. As Surgeon-General Evatt maintained in his recent lecture before the Pharmaceutical Society, it is not a question principally affecting the pharmaceutical craft, but one affecting the efficiency of the Army. We are not concerned with the details of Surgeon-General Evatt's scheme, which may or may not receive acceptance, but his general principle is, we believe, sound. The infusion of a number of skilled pharmacists into the Royal Army Medical Corps would doubtless give the officers of that Corps a readier confidence in their dispensers, and would thereby diminish an irksome responsibility, leaving them free for more important duties. The details of the scheme, however, must be carefully thought out, and must receive the criticism of experienced Army medical officers.

Hospital Reform.

It is to be hoped that some good will result from the Conference on Hospital Reform which is to be held this week on the initiative of the British Medical Association. For the past couple of years this body has interested itself in the matter, with the result that a joint committee consisting of hospital managers and of members of the medical profession has been sitting, and has been endeavouring to obtain the adoption of certain general principles of reform by hospital boards throughout the country. It is true that the most important principles have as yet hardly been agreed upon by the joint committee, but it is well that even a start has been made. There are three main points to be considered at present in questions of hospital reform, which we hope may be pressed at the Conference this week. These are the protection of the benefits of hospital treatment for the poor, the protection of the general practitioner, and the protection of the hospital staff from sweating. If the first point be attained, the other two will follow. Of them the former is by far the more important, since it is largely by their own influence that members of hospital staffs have arrived at their present position. Had they taken the trouble, as they might have done, carefully to weed their out-patient rooms even of those obviously able to pay for treatment elsewhere, the present gigantic abuse could not have arisen.

While on a visit to Liverpool last week to open the new Cotton Exchange in Liverpool, their Royal Highnesses the Prince and Princess of Wales unofficially inspected the laboratories of the School of Tropical Medicine connected with the local university.

Dr. R. T. Halliday was recently entertained by his numerous friends at a complimentary dinner in honour of his appointment as medical officer to the Glasgow police. The chair was taken by Professor Stockman.

The condition of Dr. Lapponi, the Pope's physician, is graver. He has fever, which seems to have been caused by incipient blood poisoning.

Sir Charles Ball, F.R.C.S.I., Regius Professor of Surgery in the University of Dublin, has been appointed by the Board of Trinity College as the representative of Dublin University on the General Medical Council in room of Professor E. H. Bennett. Mr. J. W. B. Hodsdon has been selected by the Royal College of Surgeons of Edinburgh as their representative in place of Sir Patrick Heron Watson.

A CLINICAL LECTURE ON POST-TRAUMATIC NEUROSES.

By T. G. MOORHEAD, M.D., F.R.C.P.I., D.P.H.,

Physician to the City of Dublin Hospital.

THE nature and extent of the nervous symptoms and signs which may follow remotely from general injuries and from local injuries of the central nervous system itself is a subject which, while constantly coming before one in everyday practice, is one which has up to the present received but scant notice in the ordinary medical text-books. Accordingly, having had a number of patients recently in the hospital who represent a few of the many and indefinite types of post-traumatic neuroses, I have selected this subject to bring before you and briefly illustrate by examples this morning. Before we proceed, however, it is necessary, in the first place, to define the sense in which I intend to use the term. As ordinarily employed, it is limited to post-traumatic "functional" nervous disturbances, and undoubtedly correctly so; but for convenience I will use it now in a looser sense to include all the late nervous conditions which may develop as a result of injuries, whether those conditions are the result of gross pathological changes or not. My reason for doing so is that in the majority of cases the problem that first meets the physician when confronted with such a patient is the question whether the case is merely a neurosis in the ordinary acceptation of the word, or is something more; and if he is rightly sceptical, it will remain as a neurosis, at any rate in his mind, until he has got very sufficient reason to form a contrary judgment. The realisation, moreover, that this question must be answered should cause one to use every care and precaution in eliciting the history of the development of the disease, and in observing from day to day the symptoms and signs of the disease and the variations in these that may develop; while careful inquiry into the exact nature of the alleged causative injury, and into the immediate sequelæ of it, should also, of course, be made. Another reason for my use of the term is that in many cases the symptoms and signs are so indefinite that, while pointing strongly to the existence of some gross change, they still do not hang together sufficiently well and are not clearly enough defined to enable one either to locate or to do more than guess at the probable nature of the lesion. Such cases remain for all practical purposes as neuroses as far as both physician and patient are concerned, except, unfortunately, that they are less amenable to treatment than are the true neuroses, and that the prognosis must be even more guarded than usual when definite pathological changes are suspected to be present.

Although not coming within the scope of the ordinary text-books, the subject of traumatic affections of the nervous system has by no means been neglected, and in connection with it there exists a copious literature to which many writers in our own country have given important contributions. One of the early authors to point out its importance was Erichsen, who in his well-known book on so-called "railway spine," enumerated the different immediate and remote lesions of the spinal cord and its membranes that he had met with in cases of contusion or concussion of the spinal cord. Many of the types that he describes are, however, chiefly of surgical interest, and as he almost entirely limits himself to spinal cases, I need not further refer to his work, since it is principally of the cerebral manifestations that I wish to speak. To this last-named aspect of the subject an important contribution was made by Crisp English in his Hunterian lectures for 1904, and innumerable records of cases and classifications are to be found in the neurological and general medical journals of every country. Dr. English records and analyses his cases in accordance with the most prominent symptoms that they presented, and where such heterogeneous symptoms are met with, this method undoubtedly has its advantages; but as the cases that I will show you, or refer to, can all be included under a few headings, I will adopt the following, which nearly coincides with that employed by Judson Bury (*B.M.J.*, 1904, Vol. I., p. 997)—viz:—(1) Traumatic neurasthenia; (2) Traumatic hysteria; (3) Traumatic insanity; (4) Cases resembling intracranial tumour or other cerebral lesion.

Traumatic Neurasthenia.—Under this heading will be grouped the vast majority of cases that one meets with. My own interest in the matter was first awakened some four years ago by observing that many patients who had undergone operations in the hospital used to come to my out-patient department months afterwards complaining of numerous and more or less ill-defined troubles, which they believed to have first set in after the operation they had undergone, and which they themselves regarded as the after-effects of the operation. On examining these individuals, I was never able to detect any organic lesion in any part of their body to account for their complaints, and so I gradually began to group them as examples of post-operative neurasthenia, though for a long time sceptical about the possibility of neurasthenia following what in many cases were minor operations. Since that time I am continually seeing such patients, in addition to the more ordinary traumatic neurasthenics, who have suffered either from injury to the head or from general injuries, and I refer to them in order to impress upon you the fact that it is not the severity of the injury that determines the subsequent symptoms. Dr. Edred Corner has lately published a most interesting paper on "Surgical and Post-Operative Neurasthenia," in the *International Clinics* (Vol. IV., Fifteenth Series, 1906), and with almost all of what he states I am in perfect agreement. In it he points out that as far as the operative type is concerned, he himself most frequently meets with it after small operations, owing, as he suggests, to the fact that they are followed by an almost immediate return to business without any intervening period of convalescence and after-treatment. He also lays stress upon the part that the use of and dread of an anæsthetic play in the production of the condition; but it is to the last factor that he mentions—namely, the personality of the patient—that I would myself be inclined to attribute the most important part in every variety of traumatic neurasthenia. He states that it is chiefly in the educated classes that one meets with the most marked cases: but I find them also amongst the working people, and perhaps more especially in the underfed, overgrown, and essentially neurotic lads from the west and south of Ireland. The more neurotic the individual is, the more will he think and brood over his injury, or over the operation he is about to undergo, and the more surely is he to suffer eventually. This effect of the mental condition on the symptoms is also to be seen in normal individuals when the question of compensation for injury is in the balance, a fact that is well known and has given rise to endless discussion and dispute from a medico-legal point of view. The symptoms that these patients present are so many that it would be quite impossible, and, indeed, unprofitable, for me to enumerate them all, and so I will content myself with referring to some of those that I have most commonly met with and regard as of most importance. They are as follows:—(1) General loss of self-con-

fidence. This symptom is, of course, common to neurasthenia of every origin, but appears in the type I refer to to be combined with a peculiar feeling that it is quite useless to return to work or business because the patient feels quite convinced that he is unable for it, and that even when he appears to be in every way well. He is suffering, in fact, from true enervation. A recent writer in the *British Medical Journal* has wittily referred to many of these cases as examples of "ergophobia," but, though willing to admit that ergophobia is common, and perhaps natural, I am sure that many of these patients are truthfully stating what they feel, for I have met with patients most anxious to return to work, apparently physically well, and yet "nervously" unable to do so. Often, indeed, the best treatment for such is to insist on a renewal of labour, for with the strained demand upon their energies thereby invoked, a sort of Schott mechanical treatment for the nervous system is established, and leads through improving phases to recovery. The same patients will often tell you that they are ill, that they know they are ill, and yet they cannot refer to a single definite symptom nor explain in any way their feelings. They complain also of a mist over their brain, of a complete inability to concentrate their thoughts, and of a fear of impending evil.

(2) Headache. This, as English points out, may be either general or local, and of various kinds. The varieties I have most often met with are boring post-orbital pain, and a general painful feeling of pressure over the entire head, accompanied by a straining sensation in the muscles of the back of the neck. This pressure sensation is apparently most distressing, and is often the most worrying symptom to the patient.

(3) Pains in other parts of the body. These are often complained of, and are frequently of a shooting character. They are by no means confined to the region of the original injury, but may be experienced in any part of the body. No physical cause for them can be discovered, and though apparently most annoying in their persistence, they do not appear in reality to be very severe.

(4) Sweating. This may be local or general, and may exist even when the individual is gaining weight and is otherwise physically in good condition. It is accompanied by vaso-motor paresis, and this last sign is often a most important one in aiding the diagnosis. When one finds that an ordinary examination of the patient leaves a series of red marks wherever the skin has been touched, suspicion that the case is a functional nervous one should at once be aroused. As an occasional result of this vascular asthenia, intermittent albuminuria may be met with.

(5) Increase in the superficial and deep reflexes is almost invariably present, especially an increase in the plantar reflex and in the knee jerk. Often some variation will be found from week to week, but the exaggeration may persist unaltered for years. The deep reflexes of the arm are also usually well marked, and as a part of the general irritability of the muscles one notices that the patient has a tendency to do things in a jerky manner.

(6) General irritability of the temper and changeability is often met with, but more commonly, I think, in brain workers than in those engaged in manual labour. Under this heading I may also mention the undue sensitiveness to alcohol and tobacco which develops, so that individuals who had previously been heavy drinkers may be compelled to give up alcohol altogether, because even the smallest amounts lead to extreme mental confusion, and even delirium. This symptom is often regarded as pathognomonic of neurasthenia, and is certainly a very constant one.

(7) Various disturbances of the special senses are met with, but the only two that I have myself seen with any frequency are neurasthenic asthenopia and tinnitus aurium

The following selected cases will illustrate the subject:—

M. R., æt., 24, a bricklayer by trade, was admitted with the following history: Five years ago, while at work, he was struck on the head by a falling plank, and was rendered unconscious. He was brought to hospital, where he quickly recovered without further symptoms developing, and was discharged in a couple of days. From that date, however, he has felt totally unfit for work, though on one or two occasions he has sought employment and has done light work for a week or two. He constantly suffers from diffuse and violent headaches, from a general feeling of weakness, and from irritability, and states that he is quite unable to touch any form of alcohol, as even a very small quantity makes him wildly drunk. At present he is suffering, in addition, from pain in his left lumbar region, which, as you will notice, is so excessive as to make him wince when the skin is lightly touched, and yet, when his attention is withdrawn, deep pressure is easily borne. You will notice that his general appearance is healthy, and that nothing abnormal can be made out in the form of scars or depression on his head. The vaso-motor nerves are evidently wanting in tone, as the skin flushes up after very slight irritation. The pain in his left lumbar region shoots downwards into the front of his thigh, but here also is more superficial than deep. Below the left knee he is this morning completely anæsthetic, and his left plantar reflex is absent, while the right reflex is exaggerated, as are both knee jerks, and also the supinator reflexes in his arms. The vascular, pulmonary, and other systems of the body are apparently quite healthy. This patient has been attending the hospital on and off for the last eighteen months, and all the above symptoms are liable to great variation. He has at times some albumen in the urine, but no casts. On account of the albumen I for a time thought that he might be suffering from some renal lesion, but X-ray examination and examination under an anæsthetic revealed nothing abnormal, and I now know that the lumbar pain may be present one day and gone the next, and that the albuminuria also, though more persistent when it does appear, is transitory. The last fact about him that I need mention is that his field of vision is somewhat contracted, and, according to the hospital notes, has been so for about three years. Many would regard count of the presence of the anæsthesia and rigidity, count of the presence of the anæthenia and rigidity, but from the general aspect of the case I prefer to consider it here.

Another typical case is this man, T. D., with whom most of you are familiar. He was admitted at first to the surgical wards with fractured ribs, and later came under my care with mild traumatic pneumonia. He has now been out of hospital for more than six months, and has gained a stone in weight, but he has begun to attend the dispensary, complaining of headache, dimness of vision, pains in the legs and shoulders, and at times in the chest. As you notice, he has got a well-marked tremor in the muscles of his arms, his patellar and supinator reflexes are exaggerated, and his plantar reflexes are excessive. Lately, also, he has begun to sweat very abundantly on the least exertion. The most complete examination fails to detect any pathological change in any of his viscera, and yet, though most anxious to do so, he feels absolutely unable now for work, and his symptoms are getting worse instead of better. He in fact returned to his employment soon after leaving hospital, and it is just within the last couple of months that he has again abandoned it.

Into the treatment of this class of case I do not propose to go, further than to say that the prolonged use of tonic drugs, with good feeding and possibly a month's complete rest at a convalescent home, bring about a cure in the majority of patients, provided they are seen early enough and can afford the rest. In cases of long standing and in the severer varieties, the prognosis is always doubtful, and the course of treatment will seldom be shorter than a period of twelve months.

Traumatic Hysteria.—This is, in my experience, a much rarer condition than the preceding, though Knapp (*Brain*, 1897) finds it even more commonly than neuras-

thenia. Much, however, depends on the distinctions that the observer forms in his own mind between the two different states, for they undoubtedly tend to merge into one another, and, as Michell Clarke points out, it is especially in traumatic cases that a combination of the two diseases (hystero-neurasthenia) is most often met with. The symptoms do not differ from those of ordinary hysteria, and consist of a general condition of emotionalism, together with occasional hysterical fits, and of numerous objective and subjective phenomena, such as localised paralysis, contractures, patches of anæsthesia and analgesia, hysterical joints, and the like.

The patient that I now show you is a good example of recurring hysterical fits apparently taking their origin from a severe concussion of the spine. As you see, he is apparently a healthy young man, and is aged twenty-one. The history that we have obtained from him and from his friends is as follows: He was perfectly healthy in every way until about two years ago, when, after a fall from a height of some feet, he was admitted to some hospital and was treated for what he was told was "spinal concussion." He states that at the time he completely lost power over his legs and sphincters, but as complete recovery took place within less than a week, we may assume that no very severe organic lesion can have been present. We may perhaps suppose that some ecchymosis of the spinal membranes and cord existed, but even these cannot have been very extensive. He soon returned to work, but ever since then he has been subject to attacks of the nature that I am about to describe, and of which we have seen several during the last few days. The attacks come on at intervals, and between them the patient attends to his ordinary work, which is that of a commercial traveller. As one of the prominent symptoms is pain of an anginoid character in the region of the heart, I may also mention the fact that the patient neither smokes nor drinks, and has been very temperate for some time in his use of tea. He was admitted here a few nights ago, having been brought by the ambulance, with the statement that he had been found sitting on a doorstep and crying out with agony. On admission he complained of a severe bursting sensation in the heart, and his face bore every evidence of the existence of severe pain, being covered with sweat and ashy grey in appearance; the neck looked somewhat swollen, the pulse was moderately rapid and full, and the respirations were 26 to the minute. He was moaning and screaming, and tossing himself about, and yet practically nothing abnormal could be made out to account for his symptoms, except that pressure over the left iliac fossa caused an exaggeration of them, and that his knee jerks were exaggerated. The usual remedies for angina pectoris were at first administered by the resident staff, but without giving relief; the symptoms, however, gradually disappeared, and the attack was followed by a copious outflow of light-coloured urine. As I have already stated, the attacks have been repeated on three or four occasions during the last few days, and I have learnt that exactly similar seizures have been observed in this patient in other hospitals. The question of malingering, of course, has here to be considered, but it is hard to see what such a patient, who is in fairly good circumstances, could gain by malingering, and his whole attitude and appearance, both in and between the paroxysms, is against this view. He has now been put on ordinary anti-hysterical treatment, and is apparently improving.

A somewhat similar case has just left the hospital, in which the hysterical outbursts were accompanied by severe pain in the left loin and inguinal region, and in which also there was a history of concussion of the spine. Under the application of Corrigan's button and the use of a mixture containing valerian, the symptoms rapidly improved, though I have little doubt that they will again recur.

Traumatic Insanity.—The influence that trauma exerts in the production of insanity is still a matter of dispute, some maintaining that it may be the direct exciting cause in an individual not in any way predisposed to mental disturbance, while others prefer to regard it as a merely additional factor in accelerating the onset of an attack in one who was already predisposed to, and, in fact, fated to become insane. That it does often follow trauma, particularly severe head injuries in which there is reason to believe that contusion of the brain has occurred, is, however, undoubted, and that it may also follow it so closely as to suggest to the ordinary observer that there is a definite causal relation in the sequence must be admitted. There is no definite type of traumatic insanity. Any of the main forms of mental aberration may be met with, but perhaps mania is more often seen at the beginning than any other type. The patient whom I showed you last week in the surgical wards has since developed maniacal symptoms, and has, in consequence, been removed to an asylum, and though I cannot, therefore, again introduce him directly to your notice, it will be no harm to recall some of the symptoms that he presented some days ago. He was, as you will remember, a man aged 33, who was admitted about two months ago, after a fall of 34 feet. It was stated that he struck the ground on his left side, and became immediately unconscious. On admission he was still unconscious, and had several contusions of the scalp, had two ribs broken on the left side, and his left forearm fractured. Soon after he had been put to bed he had several mild convulsive attacks, which involved his entire body with the exception of his face, but these ceased after half an hour, and left no paralysis. The unconsciousness lasted about 36 hours, and then the patient began to improve, and soon became able to talk and to move himself about in the bed. His sphincters, however, remained relaxed for about a month, and he has all along had an increased knee jerk on the right side, and also a slightly marked ankle clonus on the same side. He never quite regained his mental faculties, but appeared to be confused in his memory of events that took place before his accident, and of the accident itself he has never had any recollection. He sometimes also failed to understand the simplest questions, while at other times he was fairly intelligent. Since his accident he appeared to lose all definite sense of time. While in this state a few days he suddenly developed symptoms of acute mania, without any change in the physical signs taking place, and had to be removed to an asylum. Prognosis in these cases is always difficult, but the absence of any paralysis, or, indeed, of any signs pointing to extensive organic lesions is undoubtedly in this patient's favour. That the trauma was related to the insanity I think you will readily admit.

Cases Resembling Intracranial Tumour or Other Cerebral Lesion.—It is in this class that most caution must be exercised before allowing that the trauma has really been a causative factor in the case. Many individuals like to refer their symptoms to some definite injury, and may, indeed, be convinced that their reference is correct, without the real existence of any reason for it. One will, of course, not classify in this group those cases in which an obvious lesion of the central nervous system has taken place at the time of injury and has left permanent results, but rather those cases in which the nervous symptoms have appeared some time later, and while in some, such symptoms will point conclusively to a definite lesion in a definite part of the central nervous system, in a far greater number of examples it will be impossible to locate or form any definite conception of the change that has taken place. Several different types are described, such as traumatic epilepsy, late traumatic hemiplegia, and others, but it is unnecessary to enumerate them further. The actual pathological lesions that have been found are also most various, and include localised cerebral sclerosis, localised softening, thickening of the meninges, cysts of the meninges, and numerous other conditions.

The first case that I show you is a rather puzzling example. He is a man, æt. 45, who was admitted to the hospital some six weeks ago, with the following history: He had always been perfectly healthy till

about a month before admission, when he met with a bicycle accident, and got a severe shaking and a blow on the head. After the accident he made his way home and went to bed, feeling rather stunned and confused, but next morning he got up and went to his work as usual, and continued at work for about three weeks. During those weeks he suffered from constant headache, and complained on one or two occasions of not seeing properly. His employer also noticed that his gait was somewhat staggering, and that his hands were constantly shaking. These symptoms getting worse, the patient stopped work for a day or two, and then came into town to consult a doctor. On his way back his headache became very severe, and so he went to bed at once on getting home, and was found in bed in an unconscious condition some hours later. He was brought here the next day, and then was partly conscious and able to answer questions, though only in a confused and hesitating manner. He was passing everything under him, but was not otherwise paralysed, and could move his arms and legs quite freely. All his deep reflexes were dulled but present, and his pupils re-acted normally to light. The urine was quite normal, and the other symptoms of the body equally so. An examination of the retina a few days later showed early optic neuritis. Since his admission he has gradually improved to the state in which you now see him. He is at present able to walk about the ward quite easily, and talks pretty rationally, though he has not quite recovered his memory. The optic neuritis is still present, but not so marked as it was a fortnight ago; headache is sometimes complained of, but this symptom is now disappearing, and on the whole it looks as if complete recovery would take place.* The patient, I may add, persistently denies having ever had syphilis, and as anti-syphilitic treatment did him more harm than good, I am inclined to accept his statement as correct, and to believe that the trauma was the entire cause of his attack. What the exact lesion is it is difficult to imagine, but one may suppose that the attack was one of what is called "late apoplexy" following injury, and in which a hæmorrhage has taken place from a damaged vessel. The hæmorrhage, however, must be in an unusual situation, inasmuch as no motor or sensory disturbances have at any time been present.

The second case is, I think, undoubtedly one of localised sclerosis in the neighbourhood of the posterior part of the right internal capsule. He is, as you see, a man of about 60 years of age, and was admitted here for bronchitis. He was also in the hospital about a year ago suffering from the same disease, and it was at that time noticed that his left knee jerk was absent, his left leg was somewhat weaker than the right, and that he had complete anæsthesia over the greater part of his left leg and thigh. His left arm was also much weaker than the right, and the tone of its muscles increased, while, in addition, the patient was suffering from well-defined left hemianopsia. He gave us at the time a very distinct history of injury to the right side of his head some ten years ago, and says that since that time he has occasionally felt his left side to be weak, and has fallen once or twice to that side. I regarded the case at first as being most probably one of cerebral tumour, but I have now changed my view in consequence of the favourable change in the symptoms that has occurred, and look upon it, as I already stated, as a case of small localised sclerosis. At present the hemianopsia is present as before, but no optic neuritis has developed. His left arm is still weak, but his left leg has regained its strength to some extent, and a distinct though feeble knee jerk can be obtained. The anæsthesia has also gone, so that, on the whole, there has been a distinct amelioration.

The third and last case that I will bring before you is a man, æt. 51, who states that he fell a distance of 24 feet some three years ago, and was rendered unconscious for eight hours. He was detained in a hospital for a couple of weeks at the time on account of broken ribs and general bruising, but says that he had no paralysis. On returning to his work, he noticed that his right arm and right leg used to shake, and the shaking has gradually become worse till he has arrived at his present condition. As you see, he is now suffering from a sort of continuous clonic convulsive movement of the muscles of his right arm and leg. Both superficial and deep reflexes are increased on the right side, while his left side is normal. Sensation is perfect on both sides, and in other respects he is quite healthy. This patient has only just come under observation, and so as yet I have not fully made up my mind as to the lesion present, but I think it extremely likely that it is in the motor area of his left cerebral cortex, and that it may be possible to do something to relieve him.

In concluding, now, gentlemen, let me express the hope that I have impressed upon you the importance of trauma in affections of the nervous system. I fear that my necessarily brief and cursory account of the subject and of our cases may have failed to bring to you that conviction that I feel myself, but, if so, I would urge you to examine and think over such cases as you may yourselves meet, and then I think you will soon share my views. Of treatment I have said nothing, because to attempt to do so would have occupied almost all my time, and, indeed, as each case is a law to itself, and must be individually studied and treated, I could only have enumerated a number of details without laying down many general principles. Remember, also, that these cases need treatment. The neurasthenic is the most miserable of men, and yet he is frequently neglected even by his medical adviser, when much might be done for him by an intelligent appreciation of his symptoms and a carefully thought out plan of cure. Remember, also, the existence of these cases when you are called upon to treat individuals who are suffering from even slight concussion of the brain or cord. Very frequently the worst ultimate symptoms are found in the cases that originally were the least serious, and there is little doubt that this is to be attributed to the original want of adequate medical treatment and of rest.

(a) Since writing the above, the patient has further improved, and has been able to return to his occupation. The discs are still hazy, but nothing more.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The Lecture for next week's issue will be by William Taylor, M.B. Dub., F.R.C.S., Surgeon to and Lecturer on Clinical and Operative Surgery to the Meath Hospital, "On Cholelithiasis."*

ORIGINAL PAPERS.

TWO CASES OF CEREBRAL SYPHILIS WITH SOME REMARKS ON "TERTIARIES" AND THE TREATMENT OF SYPHILIS IN GENERAL.

By HENRI DARDENNE, M.D., M.R.C.P.
Physician to the French Hospital in London.

Case I.—A man, A. R., æt. 30, by occupation a waiter, consulted me at the French Hospital, out-patients' department, on October 25th, 1901, for some "spots" which he had on his body. He had suffered already from the same cutaneous affection a year ago.

The history he gave was briefly the following:—After connection, fifteen months ago, he noticed four weeks afterwards a slight sore on the anterior surface of the coronal fissure. His inguinal glands became enlarged within a few days, and as by his occupation he had to walk a great deal, they soon became painful. A few weeks after he had had the sore he was troubled with sore throat and spots all over him. He also began to lose part of the hairs of his eyebrows. He took some medicine which his doctor gave him, and after about six weeks he was quite free from the symptoms and thought himself "cured." He remained thus for about a year and then, being again troubled with the same symptoms, consulted me.

On examination I noticed that he was covered with a papular rash all over the body, and quite typical in aspect, and to the touch, of a syphilitic lesion. He had some mucous patches in the throat, sides of the tongue, mucous membrane of lower lip, and anus. He was rapidly put under the influence of mercury, and within a few weeks was quite free of these secondaries.

I lost sight of him for about six months, and then he visited me again for a papular rash in both palms of the hands and on the soles of his feet.

This was more obstinate to treatment than the previous rash He was most irregular in his attendance. In August, 1903, he was admitted as an in-patient under my care. He had then great difficulty in holding both his water and fæces and had besides patches of anæsthesia on the buttock and flexor surfaces of both lower limbs, and these last were also in a slightly paretic condition. His knee-jerks were exaggerated and ankle clonus was present. His temperature was normal. His blood-vessels were sclerotic, and the tension in them high. In short, he presented all the symptoms of a spinal lesion of the nature of a gumma or arteritis. The specific treatment was at once instituted, and this in a most energetic manner. Within four weeks all these symptoms had disappeared, with the exception of a slight difficulty in holding his water and a slight patch of anæsthesia round the anus.

Then, against our advice, he left the hospital, stopped all treatment as he thought he was being treated wrongly, and went to Italy to take a course of baths and massage. He came home after about four months, feeling much better in every respect. In August, 1904, he was found partly unconscious in bed, and paralysed on the right side. He was then taken into a general hospital. He visited me in November of the same year. His mental capacity seemed diminished, his right arm quite paralysed, rigid and contracted, his gait dragging.

The ultimate prognosis of such a case is very gloomy. Sooner or later he will certainly fall a victim to a parasyphilitic affection or to some coarse cerebral or spinal lesions, for his blood-vessels are now more sclerotic than when I first saw him in 1901. He will be paralysed all his life. The damage is done, and it is irreparable. It is a clear case of inadequate and insufficient treatment. Before he had the arteritis which caused the paralysis he used to suffer from intense neuralgic headache. He used to take large doses of phenacetine. Had he then taken iodides and mercury, he might have escaped the irreparable loss of his limbs, or at all events postponed this ultimate result for an indefinite period.

CASE II.—It is certainly a more instructive one, because I was able to follow it very closely for nearly four years. The patient was most anxious to get well. He used to follow his instructions most carefully and to the letter. The result has been, however, most deplorable. The case was, however, what we are falsely accustomed to call "a mild attack of syphilis," the secondaries being very benign in nature. The sanguine prognosis that two years' treatment is quite ample is a gross fallacy, and no words are strong enough to condemn such a dangerous teaching and practice. I can multiply the examples of such cases who, after that term of careful treatment, have come to me in the 5th, 7th, 10th, and 25th year, suffering from coarse tertiaries. Yet they were considered "cured"! The loss of a limb or of an organ by the unfortunate patient is the answer to such a pernicious view of the disease!

The patient was a man æt. 35. He was employed in one of the big London hotels. He consulted me on March 5th, 1901, for a pimple on his penis. His mode of living was regular; he was not addicted to alcohol. In appearance, he was most effeminate. He had on several occasions suffered from "rheumatic attacks" He had had pleurisy on the left side three years ago. His heart was slightly enlarged, and a slight systolic murmur was present. His urine was free from albumen and sugar, but was extremely acid. His blood-vessels were sclerotic and he had also huge varicose veins of both lower limbs. Judging by his arteries he appeared to be nearer 55 years than 35, as his age was. His lungs were healthy. Owing to his weak constitution he had been refused for his military service in France. He was also anæmic.

The history he gave was that six weeks before he had had connection, and five days ago he had noticed a slight sore in the region of the frænum. It was not painful.

On examination, I detected a typical hard chancre in that region. His inguinal glands were already enlarged, hard and indolent. When informed of this he felt it intensely, and told me that he was ready to follow all my instructions in order to get well. He afterwards always kept his word. Two months later he developed a slight roseolar syphilide chiefly affecting the front of the chest and abdomen. He had been walking a good deal, and as a result one of his inguinal glands had become swollen and painful. With rest in bed and fomentations, this inflammation soon subsided. He was extremely sensitive to the influence of mercury, his gums becoming swollen and tender after a few days' treatment with half a grain of the protiodide twice daily. I then used the intra-muscular injections with the biniodide salt and the "grey oil." This suited him well, and he never suffered afterwards from stomatitis. Let me once for all say that he was most regular in his attendance during the "successive courses" of treatment which he followed.

He was absolutely free from every syphilitic manifestation for nearly a year.

He had occasional sore throat, which always disappeared when he stopped smoking. However, though free from all outward syphilitic reminders, he used all the same to feel extremely weak and tired. He was never himself after he had had the syphilis. He had on many occasions to take iron, In winter I gave him cream and cod-liver oil emulsion. It was a case where the syphilis had caused both a moral and physical prostration. His usual energy had gone or nearly so, and the man was now a different one. In December, 1905, he complained of violent neuralgic headache, worse at night and affecting both the occipital and frontal regions. His appetite was quite gone. I put him at once under the influence of huge doses of sodium iodide and nightly mercurial inunctions—one drachm of the grey ointment for each friction. One has no time to lose in such cases, for, let me repeat it once more, such headaches occurring at such a period of the syphilis, and in a patient in such an adynamic condition are usually the precursors of grave impending cerebral trouble due to arteritis. Under this he felt rapidly better, and his appetite and sleep returned. He had then been under active treatment on and off for nearly three years. He went after this, in the middle of January 1906, to Brighton, and there, while walking on the sea front, complained to a friend that his left arm felt heavy and numb. His companion also noticed that his articulation had become thick, and his mouth appeared slightly drawn to one side. The patient was absolutely unconscious of his condition and he laughed at this state of things. When, on the following day, he returned to his work, his associates there noticed the same symptoms. He now complained to them that his left leg also felt "heavy." They told him to call on me, but he laughed and said it was nothing. He had now changed completely. He used to be always very anxious about the least little thing happening to him, and now he had become quite indifferent. I feel confident that timely, appropriate, energetic treatment would have again saved him from the calamity that was soon to befall him. In the afternoon of January 21st, exactly four days after he had these severe and grave warnings, he went upstairs to his room, and there, while trying to undress, he fell on the floor in a state of partial insensibility. On recovering, about a few minutes afterwards, he noticed that he was quite unable to use both his left leg and

arm. I was with him within an hour. On my arrival I found him in bed in a state of semi-stupor-like condition. He was drowsy, and had great difficulty in answering the simplest questions. His pupils were both dilated. His pulse was full and about 80 per minute; his temperature, 99° Fah.

His mouth was drawn to the left, and he complained of a certain difficulty in swallowing. His articulation was indistinct his left leg and arm absolutely paralysed, his patellar reflexes nearly gone. I came to the conclusion that he was suffering from the effects of arteritis with thrombotic formation. A colleague was called in the same evening who confirmed my diagnosis.

On the next day the examination of the fundus of both eyes proved to be negative. He was at once put under the influence of mercury and huge doses of iodide, beginning with 30 grains three times daily, and this within a few days was increased to 70 grains, his pulse being carefully watched all the time. It became soft and the circulation regular. He was also carefully fed with light but nutritious food at stated intervals. No stimulant was given. Within a week he could move his leg. His speech had become more distinct, and he could swallow much better. A week later he began also to be able to move his arm. Six weeks afterwards he left for the south of France. There was rigidity in the arm and his gait was "dragging." Now he is still in the same condition; his mental capacity much diminished and the sharp edge of his moral sense somewhat blunted. It is a most unfortunate case. He used to be a most attentive patient, and had been under careful treatment for three years. I never entertained much hope as to his ultimate welfare after he had had the severe headaches. This, as I have said, is a grave foreboding. My conviction now is that sooner or later he will fall a victim to some parasyphilitic affection, *i.e.*, an incurable form, or to some coarse cerebral or spinal lesion.

Remarks.

The proportion of such unfortunate cases is, according to Fournier, from 3 to 5 per cent., and this percentage is applicable to those patients alone who have undergone a long course of treatment, a minimum, say of three years, and, who, during all this time have led a carefully regulated life, avoiding all excesses and, above all, alcohol. With those who have been dissipated in their habits, and who have indulged in wines and alcohol, it is a quite different matter altogether. Why should this be so? Why should not all those who have been careful get well? A bad physique, a bad heredity, a manifestation of which is in being provided with defective arterial tubes, these account for the majority of such sad cases. They are born with tissues which just as they cannot resist the onslaught of a long chronic disease, can still less react in the right way against the syphilitic poison.

A sclerotic condition of the blood-vessels helps one to form an unfavourable prognosis as to the distant future of such a case, for the patient fulfils all the conditions favourable to his becoming affected later on or at any moment with cerebral arteritis. Parasyphilitic affections, *i.e.*, incurable syphilis, such as general paralysis and tabes dorsalis, affect to a very great extent individuals who from the beginning have defective blood-vessels or in whom the vessels have since become diseased. They are, then, the manifest production of bad arterial tubes.

This percentage of 3 to 5 of syphilitic patients developing late tertiaries more or less formidable is the result of statistics some twenty years old, and I feel confident that with our more modern way of treatment and our better knowledge of syphilis it could be further reduced. A long course of treatment is the only means we possess to effect this. Every treatment I consider insufficient if it has not lasted for at least four years.

For take as an example one hundred cases of general paralysis. In 95 per cent it has occurred in those who have had insufficient treatment, about a year or so, and in only 5 per cent. of those who have been undergoing a serious course of treatment lasting at least over three years.

The same result with tabes dorsalis. These figures are eloquent, and they are the best mathematical arguments for a long course of treatment.

Mercurialisation in syphilis can, as Prof. Fournier has said, be compared to vaccination. The first is a preventive, which no one can doubt, against the very vast majority of possible future syphilitic affections, but, like vaccination, it is a temporary preventive. The patient has to be "mercurialised" in order to become immune for a time more or less long against the noxious influence of the syphilitic intoxication. The treatment, as Fournier lately said, could be divided into different stages:—1st, immediately after infection, a course of treatment lasting two years, and this whether the patient is troubled with secondaries or not; 2nd, a second course of treatment lasting the whole of the fifth year of the disease; 3rd, stop again all treatment for a few years, and by the eighth or seventh year again resume treatment for another year. Such, in brief is the treatment, which of course has to be modified according to circumstances and individual peculiarities.

Personally, I consider it a perfect heresy to say that two years' treatment is quite sufficient. It may be sufficient for the present welfare of our patient, but what about his future? How many cases of syphilis have we not seen which have been treated for that brief period, and which, after five, seven, ten and twenty-five years have come to us at that stage, affected then with most formidable tertiaries costing them a limb or an organ? Yet they were considered "cured"! Their case was looked upon as a mild one!

Mild secondaries, though it may seem paradoxical to say so, are the worst cases. Once the patients are no longer troubled with any outward manifestation, they abandon all treatment. On the contrary, one with constant, troublesome and repeated secondaries, and especially the late secondaries lasting on and off for a few years, and necessitating constant treatment, has more chances to escape the tertiaries, for his syphilitic poison has been attenuated by a successive and often repeated course of treatment. The effect of a mercurial course of treatment on a patien is but temporary, and the case mentioned by Tushmann corroborates this fact to the fullest extent. It is that of a syphilitic woman becoming pregnant seven times. She is not treated at all, and each time she gives birth to a syphilitic child. She again becomes pregnant for the eighth and ninth times, she then undergoes a most energetic course of treatment, and she has after this the satisfaction each time of giving birth to a healthy child. She again becomes pregnant for the tenth time, and thinking she is "cured" neglects all treatment. She once more gives birth to another syphilitic child, who dies at the sixth month.

Finally she is pregnant for the eleventh time, undergoes a course of mercury, and again gives birth to a healthy child. This case needs no comment It looks as if it had been manufactured with the sole object of proving that a mercurial treatment has, in order to act as a sure preventive against possible syphilitic consequences, to be long and often repeated.

Again, we know that general paralysis, which is the most dreaded tertiary syphilitic manifestation, and all the more so as it is incurable, is most prevalent between the sixth and the twelfth year after the syphilitic infection. Would it not be possible to a certain extent, by a rigorous course of treatment during the fifth and seventh years to reduce the percentage of those unfortunates who fall a victim to that dreadful calamity? It would, at all events, be worth our while to try it and give the benefit of the faintest chance to our patients. It would certainly be better than telling him that he is "cured" after a course of two years' treatment. For what happens? They neglect all hygienic rules that a syphilitic should observe, and they live happy in a fool's paradise with the sword of Damocles hanging over their heads, and with the greatest possible chance of falling a victim to general paralysis

or tabes or some coarser lesions entailing the loss of a limb or an organ. Let me, then, again say that the best safeguard, the only safeguard, which a patient can possibly have to avoid these two afflictions, resides, and resides alone, in a long course of treatment which has been methodically carried out and at successive periods.

THE CAUSATION AND TREATMENT OF SOME HEADACHES. (a)

By WILFRED HARRIS, M.D.Cantab., F.R.C.P., Lond.,

Physician to the Hospital for Epilepsy and Paralysis, London, etc.

The varieties of headache considered on this occasion are the paroxysmal or periodic headaches and those dependent upon some form of toxæmia. Many periodic headaches are of the form known as true migraine, an hereditary neurosis, probably dependent upon some paroxysmal vaso-motor derangement. After describing the mode of onset and the type of headache, Dr. Harris remarked that these migrainous headaches very commonly commence in early life, and last until well past middle life, recurring at varying intervals, but usually diminishing in severity and frequency as the years pass. If gout, or tuberculosis, or other cause of frequent pyrexia supervene, the headaches as a rule disappear. The attacks often come on without any previous warning, just as epileptic attacks may do, the patient being apparently in his usual health; yet they are liable to be precipitated by the same causes that are liable to bring on a fit in an epileptic subject—namely, great excitement, late hours, a crowded room, a bout of drinking, or in women, the menstrual period. Constipation is by no means always present, the tongue is often clean at the commencement of the attack, and there is no reason to ascribe this class of case to a toxæmia of intestinal origin. If the headaches are of frequent recurrence, it is best to treat them between the attacks with bromides on the same lines as a case of epilepsy would be treated, with a mixture of the three bromides. The actual headache is often best relieved, if taken early, perferably during the stage of scintillating scotoma, by a stiff dose of butyl chloral hydrate and phenazone. Another drug that may often bring almost immediate relief is nitro-glycerine, by reducing the cerebral arterial pressure. Dr. Harris next discussed the pathology of migraine, giving reasons and describing cases which supported the hypothesis that in migraine there is a primary stage of arterial spasm, which is succeeded by vascular engorgement which directly produces the headache. He next referred to periodic headaches, which may resemble true migraine somewhat closely, and yet are less dependent upon an hereditary neurosis and paroxysmal vaso-motor spasm than upon some peripheral cause, which by its local irritant effects may set up reflexly a migrainous attack. These cases in their pathology would be strictly analogous to reflex epilepsy, such as convulsions dependent upon the peripheral irritation of worms, the irritation of a scar, etc., and he made the point that although the attack of migraine resembles true migraine, yet the peripheral cause in these cases is the most important element in their causation, and the removal of this may be followed by complete cure of the periodic headaches. Toxæmic headaches may be due to the administration of drugs, as alcohol, iron, nitro-glycerin; or may be dependent on an acute infective process, as typhoid, small-pox, pneumonia malaria, or influenza. Thirdly, it may be due to faulty metabolism, in organic disease of the liver, as alcoholic cirrhosis, or to a functional derangement of that organ. The headache that is so common a feature in gouty conditions is perhaps partly due to a deranged liver action, by which the purins and other uric acid antecedents are permitted to circulate in the blood, and partly to a faulty diet containing an excess of those bodies. Possibly excess of carbohydrate foods may also predispose to headaches, the condition lately described as hyperpyræmia.

THE OUT-PATIENTS' ROOM.

METROPOLITAN HOSPITAL.

Arterial Tension.

By LEONARD WILLIAMS, M.D., M.R.C.P.,

Assistant Physician to the Hospital; Physician to the French Hospital

This woman, whose age is 65, has been coming to the hospital for the last three years. When she first came her chief complaint was dyspnœa on exertion. During the period that she has been coming her notes show that at various times she has had attacks of bleeding from the nose, hæmatemesis and hæmoptysis, and on the day on which I first saw her she told of an attack which had evidently been truly anginal in character. This was about a year ago, and she then complained a good deal of insomnia. On examination I found that her heart was enlarged downwards and to the left; her aortic second sound was very much increased; there was dulness over the manubrium sterni; her systolic blood pressure, as registered by Oliver's Hæmomanometer, was 200 mm. Hg.; and there was no albumen in her urine. Now, this case is instructive from many points of view. Three years ago there were not very many of us who paid particular attention to the matter of high blood pressure, and it is, therefore, no reflection upon my predecessor in charge of this case to say that when the patient first came to the hospital she presented symptoms which all of us ought in these days to recognise as typical of unduly high blood pressure. Dyspnœa, the dyspnœa of slight exertion, especially when accompanied by a history of bleeding from anywhere—whether it be from the nose, from the stomach, or from the lungs—is so suggestive of high arterial tension that it ought always to lead to the use of the manometer. It is very unlikely that in those days the manometer, even if the hospital had possessed one, would have shown the same degree of blood pressure, namely, 200 mm. Hg., which it recorded when I first saw her, but then matters had unfortunately progressed with her in the interval.

On the majority of her very frequent visits to the hospital her urine was examined, and on no occasion was any albumen discovered. This is an important point, because so many people still persist in regarding high blood pressure merely as a symptom of chronic interstitial nephritis. Such a view of the matter is, however, a ridiculously narrow one. High blood pressure occurs independently of any organic lesion either in the kidneys or elsewhere. Either by irritation of the vessel walls themselves, or by interference with the centre in the medulla, certain toxins give rise to contraction of the peripheral arterioles, and the blood pressure is thus raised. If it be not diminished organic changes are sure to take place. In the smaller arteries the degeneration which we recognise as arterio-sclerosis is particularly apt to occur. Arterio-sclerosis, as you know, is a very feminine process, inasmuch as it is a very capricious one. It may select the arteries in the renal area, or those in the hepatic or other areas, or it may be generalised. High arterial

tension will also cause damage to the larger arteries, and the aortic arch is peculiarly susceptible to the degenerative influence of high blood pressure. In the larger arteries the result is not a sclerotic, but an atheromatous, degeneration.

Now, the high blood pressure in the case of this patient, which we may assume to have been at first functional, has caused degeneration, not in her smaller arteries, but in the ascending aorta. She has a very definite dulness at the manubrium sterni, which extends rather to the right. I do not think this process will now go any further, because since I have been treating her her symptoms have very much abated; her blood pressure has fallen from what it was, namely 200 mm. Hg., to 165 mm. Hg., she has had no more attacks, and her breathing is very much more comfortable. Of course, when these cases go untreated the danger is that the atheromatous patch in the ascending aorta may yield, and give rise to an aneurysm; or that the atheromatous process may travel downwards, involving the aortic ring and the aortic cusps to give rise to a double murmur at the base; or—what is even more serious, and what we have to fear to some extent in the case of this woman—the atheromatous process may travel along the coronary arteries and interfere with the adequate blood supply to the heart, causing angina pectoris and fibrosis of the myocardium.

So far as treatment is concerned, one of the most important items is diet. The toxins which give rise to high arterial tension originate in the gastro-intestinal tract, and there seems no doubt that meat foods contribute more powerfully to the manufacture of these toxins than foods of other kinds. I always tell patients of this type that they may eat anything except what has contained blood—that is to say, I endeavour to make them into lacto-vegetarians. Milk and milk foods should form their staple diet, but I allow any fruit and vegetables, and eggs, and cheese. In giving directions to patients it is always well to make such directions as simple as possible, and the point that I insist upon is that they should eat nothing which has contained blood. Tea and coffee certainly both tend to raise arterial tension, though not for long. In bad cases, therefore, it is well that they should be avoided.

So far as drugs are concerned, iodide of potassium in large doses of from 10 to 20 grains, three times a day, certainly is of considerable value, but it is probable that its efficacy is due as much to its eliminative power as to any direct action which it may have upon the arteries themselves. It removes the offending poison and gives the vessels the opportunity of righting themselves. For any individual attack (such as this woman appears to have had) of an anginal nature, nothing can compare to nitrite of amyl. Its action is, however, very transitory, and there is therefore no use in prescribing it if we want to produce a sustained effect. The best drug for producing anything like a sustained effect is erythrol tetra-nitrate, which may be given in doses of half a grain, or even a grain, three times a day.

If the patient suffering from a condition of this kind is in a position to travel for the sake of her health, then it is most important that you should remember that she must not be sent to bracing climates, or climates of high altitude. The proper places for patient's suffering from high arterial tension, or any of its consequences, are those which are commonly called relaxing. The stations on our own south-west coasts, from Bournemouth to Land's End, offer admirable examples of the types of climate which suit patients of this class. If you can send them to a place where by means of warm baths, judiciously administered, the effects of the climate can be enhanced, then so much the better, because warm baths do these people a great deal of good. It is not difficult to understand that a warm bath, inasmuch as it dilates the blood vessels over an enormous area, gives considerable relief to the heart. Bath, in Somersetshire, Sidmouth, in Devonshire, and Bournemouth, in Hampshire, are all places where baths as well as climate may be called in to assist in the treatment of these cases, because it is necessary to insist that these cases must be treated. High arterial tension may leave its mark upon the smaller arteries or the larger arteries, but, if it be not relieved, it inevitably leaves its mark upon the heart itself. The central organ must get the blood to the periphery, and when the arterioles are contracted, its work is very largely increased. It will put up with this increased amount of work for a long period, but after a time, underfed and overworked, it bends and not infrequently breaks.

The main object, then, to which treatment must be directed is to relieve the strain on the heart by dilating the peripheral vessels. Do not, I beg of you, make the common mistake of meeting this difficulty by endeavours to stimulate the heart. If you will relieve its burden, the central organ will right itself. If you do not relieve its burden, then, by giving digitalis and its congeners, you are only whipping the tired horse and hastening its inevitable collapse.

OPERATING THEATRES.

GREAT NORTHERN HOSPITAL.

Operation for Pes Cavus.—Mr. Peyton Beale operated on a man, æt. 22, complaining of very marked pes cavus in both feet; there was a certain amount of talipes equinus also present. The patient was a ship's foreman, and he stated that the deformity had been gradually coming on during the last three or four years. On examining the feet it was evident that the plantar fascia was exceedingly tense, and that as far as the cavus condition was concerned this only was responsible. In walking he could put his heels to the ground, but in doing so complained of a good deal of pain in the soles of his feet. The legs were very carefully examined in order to ascertain if there was any tonic contraction of the calf muscles, but nothing of this sort was to be found. The region of the sciatic nerve was also carefully investigated, but nothing could be found which could in any way cause irritation in any part of that nerve. The following operation was performed:—The house surgeon having extended the foot and flexed the ankle as far as possible, a sharp-pointed tenotomy knife was introduced into the sole in five or six places, and the tense bands of the plantar fascia freely divided. When this was done there was a very marked improvement in the form of the foot. A dressing was applied, and the foot was put up on a back splint with a right-angled footpiece, so made that the foot was kept in a position of marked inversion, but at the same time at right-angles to the leg. It was intended that this should be kept on for ten days, and that the feet should then be put up in plaster of Paris. Both feet were operated on and treated in the same manner. Mr. Beale said that there was nothing in the history of the case to account for the condition. He had seen more or less similar cases before. In one he remembered there was a neuromatous tumour close to the point where the sciatic nerve divided, and in another there had been a large gumma in connection with the deep fascia of the leg between the gastrocnemius to the soleus, which had led to extensive cicatricial contraction in both those muscles. In these cases, of course, only one foot was affected. He said he considered it wiser to leave the Tendo Achillis for the present, and if he found it necessary to partially divide it in order to secure better position for the foot, he should partially divide the Tendo Achillis later on. He remarked that whenever he used a back splint with a footpiece he always had the footpiece so fixed that the foot was applied to it in a position of marked inversion, and since he had adopted this plan he found that the patients never complained of any discomfort in the foot while the splint was being used.

TRANSACTIONS OF SOCIETIES.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF OBSTETRICS.

President, R. D. PUREFOY, M.D., F.R.C.S.I. Sectional Secretary, HENRY JELLETT, M.D., F.R.C.P.I.

MEETING HELD FRIDAY, NOVEMBER 16TH, 1906.

The PRESIDENT (Dr. R. D. PUREFOY) in the Chair.

SIR WILLIAM SMYLY showed a fibro-cystic tumour of the broad ligament weighing 13¼ lbs. He said that such tumours must be rare, as this was the first he had met with.

Sir ARTHUR MACAN asked whether the fluid from the tumour coagulated on being allowed to escape. The feeling of fluid in the tumour was an extraordinary one.

The PRESIDENT recalled a specimen shown to the Academy some years ago, on which occasion Sir Arthur Macan remarked that surely there was fluid in it. A section was made at once, and there was not a trace of fluid. He mentioned the case as showing that sometimes a tumour was met with which imparted a misleading sensation to the finger on examination.

Dr. E. H. TWEEDY showed (*a*) tubal pregnancy, (*b*) perithelioma of uterus, (*c*) fibroids undergoing sarcomatous degeneration.

Dr. ROWLETTE said that perithelioma had not been described until within the last few years. It was extremely likely that the tumour had been seen previously, but had been unrecognised. He recalled a case of tumour of the ovary presenting remarkable resemblances to that before them, which had been put before the Academy the previous year by Dr. Tweedy. The fibroid tumour was interesting on account of recent discussion as to whether such change really took place. From the naked eye appearance one would not judge it to be sarcoma, but in the broad ligament there was a mass of softened tissue which looked extremely malignant. A section from the upper part of the tumour showed not fibrous tissue at all, but a mass of sarcoma cells. A section from the lower part of the uterus showed simply a degenerating mass of fibrous tissue. The case was, he thought, correctly described.

Dr. KIDD asked if there was any method of knowing, before a section was made, whether the tumour was of a malignant nature or not; otherwise, except in extreme cases, the operator would run a great risk of infecting his patient.

Sir W. SMYLY thought that the splitting of such tumours was not free from risk. Within the last three years he had lost a patient through pus infection from an abscess which had been burst during operation.

The PRESIDENT said that the bisecting of the uterus in some cases allowed them to secure the uterine vessels and avoid injuring the uterus. He recalled a case of removal for fibroid of the uterus. There was nothing in the aspect of the uterus to suggest that it was the seat of malignant disease. The patient made a good recovery from the operation, but when the uterus was examined afterwards it presented two large foci of malignant disease. He felt that if he had bisected the uterus he would have realised the state of affairs, but he would have run the risk of infecting the patient.

Dr. TWEEDY replied.

The PRESIDENT then read his Introductory Address, in which he referred to the work of the preceding session, noticing the various communications read by the members, including papers read by Dr. Delaharpe, of Bonn; Dr. Sheill, of the Coombe Hospital; Dr. Holmes, of the Rotunda; Dr. Ashe, of the Adelaide; and Sir A. Macan, and the reports of the Rotunda Hospital—in one of which is recorded a case of spontaneous inversion of the uterus occurring in the hospital, while the patient was under observation. The theories recently adduced as to the causes of eclampsia were mentioned, and the value of the old treatment by bleeding, followed by saline transfusion, was emphasised. The views recently put forward by Halban as to the secretion furnished by the ovaries and placenta, and its influence on the genital organs of both mother and child, were noticed; also the supposed influence of luteum tissue in causing the development of hydatidiform moles, malignant or otherwise. Reference was made to three cases of accidental hæmorrhage, recently reported, all of which ended fatally, and in all of which autopsy showed incomplete, external rupture of the uterus had taken place. Dr. Savage's recent paper on "Ovarian Hæmatomata" received very favourable notice, and attention was directed to the renewed interest in, and good results obtained by, serum injections in puerperal sepsis.

REPEATED TWIN ABORTIONS AND VENTRO-SUSPENSION.

Dr. SPENCER SHEILL then read a paper on repeated abortion and ventro-suspension.

A woman, æt. about thirty years, married four years, has had four abortions, all at about the tenth week, the first one being twins. There is a family history of twins—she has twin sisters. On the 3rd of May, 1905, he curetted the patient for an incomplete abortion, when she came under his care for the first time, and at that time he made the diagnosis of acute retroflection with a fibroid, and recommended operation, as she was very desirous of having a living child. She agreed, and on the 23rd of the following June he removed a pedunculated fibroid about the size of a hen's egg, which was attached to the fundus, and did a ventral suspension. The patient menstruated normally on July 19th and August 21st, her husband being away in the country. He returned, and cohabited with her for the first time since the operation on September 1st, 1905, with the result that Dr. Sheill delivered the patient of a child, which showed every evidence of being full term, on June 16th, 1906, so that the conception must have taken place on or about September 16th, 1905—*i.e.*, sixteen days after the husband's return. But on October 21st, 1905, exactly two calender months after the last menses, the patient had a uterine hæmorrhage, and with it came away an ovum of about six weeks development. The hæmorrhage was not very profuse, and soon ceased. There was no pain, so active interference was withheld. The patient was taking potassium chlorate at this time. No further menses occurred, and on examination early in January, 1906, Dr. Sheill diagnosed a "uterus large enough for four and a half or five months' pregnancy, which might be a mole or a twin of the ovum aborted last October." With regard to the success of the operation itself, it is interesting to note that the ventro-suspension caused no pain, unusual vomiting or frequency of micturition during gestation, and that there was no dragging on or alteration in shape of the uterus other than a slight dimple at the fundus. The labour was uneventful, and the ventral scar showed no signs of weakness. A vaginal examination a month later showed the uterus to be normally involuted and in perfect position. An enlargement of the thyroid gland has been described in infants born of mothers who have been taking potassium chlorate during pregnancy with a view to prevent abortion. There was no such enlargement in the infants' thyroid in this case.

Sir W. SMYLY said he believed the displacement was a cause of complications. He approved of suspension, but many cases of retroversion—especially those which occurred after delivery—got well if treated with a pessary. He had no doubt that the living child was the result of Dr. Sheill's treatment.

Professor A. SMITH said he thought the displacement was due to the tumour dragging on the wall of the uterus. Dr. Sheill had acted wisely in removing the tumour and preserving the uterus. Of course, one could not say whether it was absolutely necessary to have suspended the uterus. He had removed fibroids from the back of the uterus, and it had righted itself after a time. Cases were well-known in which one of the causes of the displacement of the uterus was the weight of a fibroid tumour dragging on it, and he

knew of a series of cases of suspension of the uterus where pregnancy did not occur. He was a believer in suspension, but it was difficult to decide which method to follow.

Dr. Jellett said that for the last couple of years he had been doing a considerable number of radical cures of backwards displacement of the uterus, and of them five patients had been confined in hospital after operation. In no case was there any trouble. He was inclined to the belief that, after a simple ventro-suspension, if the patient became pregnant, a return of the displacement was likely to occur. He had found no difficulty in Alexander's operation, and in no case had the immediate results been otherwise than excellent. He was therefore in favour of the Alexander operation in simple uncomplicated cases of retroversion of the uterus. There were, however, a number of cases in which it was entirely inapplicable, among which Dr. Sheill's case was, he thought, included.

Sir A. Macan said the paper opened up the whole question as to whether every case of retroflection was to be operated on. They should try to settle the indications, and until this was done he preferred treatment with the pessary. He considered the Alexander operation more reasonable than fixation against the abdominal walls. When the cornu of the uterus had been fixed almost into the internal abdominal ring, if the woman became pregnant, parts which were almost touching became stretched five inches, and he confessed that it appeared very strange to him that they should go back again after such stretching. The whole question was not near solution, and he was anxiously looking to some experience that would help him to make up his mind as to what cases he should operate on, and the best method.

Dr. Ashe said it was impossible to say if Alexander's operation would be a success until one had ascertained by inspection the condition of the round ligaments.

Dr. FitzGibbon said that vaginal shortening of the round ligaments was not often mentioned, although it was easy to perform. He had seen a case two months afterwards, and the uterus was perfectly in place. By such a method an abdominal scar was avoided; but, if there had been pelvic inflammation, there would probably be adhesions between the uterus and the pelvic walls, in which case it would be necessary to open the abdomen.

Dr. Hastings Tweedy thought Sir Arthur Macan had taken a rather gloomy view of the many disastrous possibilities of ventro-suspension. It never occurred to him (Dr. Tweedy) to look forward with the least anxiety to pregnancy or labour following this operation. If a sufficient number of stitches were not placed in the uterus, a relapse would follow delivery. He thought therefore the suspension should be made by two separate sutures. One could never say that occlusion of the tubes was not present until the abdomen was opened, and for this reason he considered Alexander's operation much inferior to the ventral suspension.

Dr. Horne thought that if there were adhesions they were bound to interfere with them; but, if not, he was inclined to replace the uterus and insert a pessary, even if the woman became pregnant.

The President said that no single method could be considered free of the possibility of giving rise to complications. He remembered the case of a woman who had been operated on by Mr. Alexander himself, and who had aborted three times in the two succeeding years. It was obvious that the round ligaments might stretch and allow the recurrence of the displacement. The peritoneal adhesions which were formed in ventro-suspension might also stretch and give rise to various risks.

Dr. Sheill then replied.

The following card specimens were shown:—

Dr. E. H. Tweedy—(*a*) adeno-carcinoma of vulva; (*b*) epithelioma of vulva; (*c*) adenoma of uterus; (*d*) epithelioma of cervix; (*e*) myomatous uteri, 8; (*f*) pyosalpinx and salpingitis, 6; (*g*) ectopic pregnancies, 2; (*h*) ovarian cysts, 10.

THE LIVERPOOL MEDICAL INSTITUTION.

Meeting held Thursday, November 22nd, 1906.

Frank T. Paul, President, in the Chair.

NO-LOOP GASTRO-ENTEROSTOMY.

Mr. K. W. Monsarrat read a paper on Posterior Gastro-enterostomy, with special reference to its performance without a loop. He discussed the functional results obtained by this method, particularly in regard to the absence of regurgitant vomiting, and illustrated his paper by clinical cases.

The President stated that he had had the opportunity of seeing the condition present in three cases of gastro-enterostomy, suffering from regurgitant vomiting, and failed to find an anatomical explanation of the trouble. In these and other cases he had met with there was only one common element, and that was gastric atony. The patients were either neurotics or exhausted cancer cases, and the most perfect "no loop" operation was no bar to this cause of failure in such people. In past times and recently on special occasions he had done the anterior operation, altogether perhaps twenty times, and it was noteworthy that he had not met with regurgitant vomiting following the operation. When the trouble occurred it could be cured by entero-enterostomy, especially with partial occlusion of the ascending limb of bowel between the intestinal anastomosis and the stomach. Such an operation, however, was difficult to accomplish after a genuinely "no-loop" operation.

Mr. Thelwall Thomas said he had always performed posterior gastro-enterostomy by the "no-loop" method, and considered the anterior operation and the Y-method open to grave objections. In only one case had he observed any symptoms suggestive of "vicious circle" and it was with difficulty that he had then performed entero-enterostomy.

Mr. R. W. Murray and Dr. E. T. Davies also spoke.

SPONTANEOUS FRACTURE OF URINARY CALCULI.

Dr. T. R. Bradshaw related a case of Spontaneous Fragmentation and Evacuation of Uric Acid Calculi in a gentleman, æt. 80. Fragments had been passed at intervals extending over nearly a year. Calculi had been located previously in one kidney by the X-rays, and there had been attacks of renal colic and hæmaturia. He believed, with Prout, that uric acid calculi frequently had a radial structure which facilitated fragmentation, and that the latter was brought about by the action of healthy urine containing a minimal quantity of nitrogenous waste products. He thought that urine of this character was not common in the subjects of calculi; hence the infrequency of spontaneous disintegration. He considered that the attempt to dissolve calculi by administering alkalies was useless, and might be injurious by tending to the deposition of phosphates on a uric acid stone.

Mr. George G. Hamilton showed a patient with Erb's Paralysis caused by a fall by which the brachial plexus was in part ruptured. Mr. Hamilton remarked that only three cases had been previously reported.

THE GENERAL MANAGEMENT OF ABDOMINAL SECTION CASES.

Dr. W. Blair Bell read a paper on "The General Management of Abdominal Section Cases," in which he first discussed the personal equation of the patient, which, he said, must enter largely into all considerations of treatment and prognosis. The preparation of the patient, with a detailed consideration of the value of atropine before the administration of the anæsthetic; the anæsthetic, and the reasons for preferring ether to chloroform; together with points in connection with the technique of general operative procedures, especially in septic cases, were fully dealt with as essentials to be observed in the prophylaxis of post-operative complications and discomfort. He then described the routine post-operative treatment of a straightforward case, pointing out the value of frequent changes of posture, of early feeding with glucose solution and egg-albumin in water, and

the free use of salines by the rectum to prevent shock and thrombosis. He also discussed the treatment of the chief post-operative complications, indicating that most of them could be prevented by the methods of prophylaxis to which he had alluded.

Dr. H. BRIGGS said it was needless repetition, in any discussion on abdominal surgery, to mention the precautions and preparations which are as applicable to it as to general surgery. The results of the former illustrated the accommodating vitality and resourcefulness of the healthy peritoneum, of which the general pathologist, in more recent years, had so frequently reminded the surgeons. The Trendelenberg position was now almost universally appreciated. On the etiology and treatment of post-operative, gaseous, intestinal distension there was now as much obscurity as ever; hence we are unprepared to receive the often confused and worthless reports of therapeutical and surgical resources.

SIR JAMES BARR said that he had many years ago recommended the systematic use of Atropine before the administration of chloroform. He thought strychnine was very much abused in the present day, but that morphia, in small doses, was very valuable in all abdominal affections, and did not check peristaltic action in the same degree as was generally supposed. He was pleased to find that Dr. Blair Bell took systematic records of blood pressures, as the impression even of the educated finger was often very deceptive, especially when the pulse was of small volume. In cases of collapse and shock the life of the patient often depended on the maintenance of the blood pressure, and about the best drug we possessed for that purpose was adrenalin; unfortunately the action of the drug was comparatively evanescent, and it was very difficult to get its physiological effect except when it was injected into the veins, or, in abdominal operations, by injecting it and normal saline solution into the peritoneal cavity.

MR. THELWALL THOMAS was a warm advocate of the administration of atropine before ether. He criticised adversely the Clover type of inhaler, which compelled the patient to breathe his own putrid exhalations as well as ether.

Mr. G. P. NEWBOLT, speaking of general peritonitis, advocated rapid operating and washing out, as by this method time was saved and less damage done than when extensive dry swabbing was attempted. In some cases he regarded morphia and alcohol as of the greatest value. His experience in draining gut for distension had not been favourable, and in some cases of marked distension the patients had recovered without the adoption of this procedure.

Dr. T. B. GRIMSDALE had come to the conclusion that one had only to travel far enough in order to have dispelled and refuted all those little fads that one considered of such importance. As long as the true general principles were adhered to, the small details could be varied *ad infinitum*. If an operation was well performed, it seemed as if one could do almost anything one liked in the after-treatment. He thought the thing to aim at was simplicity.

Dr. W. FINGLAND referred to the administration of atropine before ether as a most valuable procedure, which he had adopted as a routine practice for many years. It had the effect of abolishing salivation, diminishing after-sickness, and facilitating the administration of the ether. In dental surgery it was equally valuable, as the operator had only the hæmorrhage from the extractions to deal with.

Dr. F. W. BAILEY thought that Chloroform suited some cases better than ether. Ether should be given by the open method, preferably with an Allis inhaler; as this method avoided the difficulty of salivation and reduced the risk during the operation and the danger of subsequent respiratory troubles. He generally began with chloroform in order to get complete relaxation of the muscles, which was so important in abdominal operations, and then went on with ether.

Mr. R. W. Murray, Mr. G. G. Hamilton, and Dr. T. Davies also spoke.

CENTRAL MIDWIVES BOARD.

MEETING HELD NOVEMBER 29TH.

The President, Dr. CHAMPNEYS, in the Chair.

THE first matter was the payment for training of Midwives by County Councils, and the Secretary read a question put by Mr. Bateman Hope, asking the President of the Local Government Board whether the Board had formed the opinion that it was illegal for County Councils to pay for such training either out of the county fund or out of the funds set apart for the purposes of higher education, and, if so, on what grounds.

Mr. John Burns had answered:—"It would seem to the Local Government Board to be competent for a county council to incur expenditure for this purpose in exercise of the powers conferred on them by Section 2 of the Education Act, 1902, if, after consultation with the Board of Education, it appeared to them desirable to do so. But they are not aware of any legal authority which would enable a county council to incur any such expenditure apart from these powers.—November 21st, 1906."

The Board then dealt with the recommendations of the Standing Committee. A letter was read from Dr. Swayne, of Denbigh, saying that the inability of the Welsh candidates to pass was not due to the examination being in English, but to want of practical knowledge. The Board, however, in answer to an appeal for a translation from the Denbighshire County Council, authorised such translation to be made.

The vexed question of doctor's fees appeared again in the form of an enquiry from a midwife. One doctor would not come, and another asked a two guinea fee, which, of course, the poorer patients could not pay.

In answer, the Board could only send the usual reply that they regretted inability to help.

Dr. Sergeant, County M.O.H. for Lancashire; sought information as to cases of puerperal fever occurring *the day after* the midwife left. But to this query the President decided that they could only prosecute when actual negligence could be determined during the regulation ten days.

A letter from Dr. Armstrong, M.O.H. for Newcastle on-Tyne, bore upon practically the same question—the teaching and supervision of uncertified midwives—but here again the President pointed out the Board's inability to deal with such women until 1910.

The subject of multiplying centres to meet the requirements of a small number came up again, this time from Newbury.

Dr. PARKER YOUNG remarked that the Board ought to give more attention to such appeals. Here were women, anxious to be trained, seventeen miles from the nearest centre. Dr. Thompson, a man holding high qualifications, had volunteered to teach them, and had been rejected. The other doctor in Newbury did not care to hold a class unless twelve candidates could be found. Midwives were wanted, and it was clear the Board were putting obstacles in the way.

Miss Paget was in favour, also Miss Wilson, of a Newbury centre, though Sir Wm. Sinclair and Mr. Ward Cousins who were not present, have always protested against the multiplication of centres.

The PRESIDENT thought the Board were quite right in refusing, but as Dr. Parker Young and one or two others seemed to think an injustice had been done, he agreed to a motion that Dr. Thompson should be asked to apply again for the post.

The Marchioness of Winchester, Vice-president of the Hants Nursing Association, wrote objecting to the term "suspended," saying it was derogatory and savoured of "misconduct."

Miss PAGET remarked that the term was in great disfavour in many centres.

Answer was returned that the terms "suspend" and "suspension." had definite technical meanings as laid down by the Midwives Act.

The first physician of the Cama Hospital, who enquired by letter why the Hospital could not be sanctioned as a centre, had reply that it was contrary to practice to give reasons.

The proceedings then terminated.

GENERAL MEDICAL COUNCIL.

EIGHTY-FOURTH SESSION.

First Day; Tuesday, November 27th, 1906.

Dr. MacAlister, President, in the Chair.

The President informed the Council, with regret, that he had received communications from two members of the Council, Dr. Barrs and Dr. Cocking, intimating their inability to be present during the session on account of ill-health.

The official notifications of the appointment of two members to the General Medical Council were then read by the Registrar :—

1.—We, the Royal College of Surgeons of Edinburgh, in pursuance of the power given us by the Medical Act, 1886, do hereby appoint James William Beeman Hodsdon, Esq., to be a member of the General Medical Council of Medical Education and Registration of the United Kingdom for the term of five years from the 21st day of June, 1906.

Charles Watson MacGillivray, M.D., President.

Mr. Hodsdon was introduced to the Council by Sir John Batty Tuke.

2.—We, the University of Dublin, in pursuance of the power . . . . . do hereby appoint Sir Charles Ball . . . . . for the term of one year from the 23rd day of June, 1906.

R. Y. Tyrrell, Registrar.

Sir Charles Ball was introduced by Dr. Little, and cordially received by the Council.

The President then delivered the following address :—

Gentlemen,—Let me begin by offering you my congratulations on the improved physical conditions under which you assemble to-day. The plans for the enlargement of this chamber, submitted by the Office Site Committee last May, have during the summer been carried out under its direction. . . .

Of the members who were accustomed to meet with us in the old chamber, three are missing from the new. You will allow me to say a few words about each.

Our senior member, Sir Patrick Heron Watson, *magnum et venerabile nomen*, who since 1882 has sat with us as the representative appointed by the Royal College of Surgeons of Edinburgh, retired at Midsummer after twenty-four years of distinguished service. We are the poorer for the loss of a Councillor whose grave wisdom, and whose stately eloquence upon fit occasion, were but the expression of his high conception of professional duty, and of his sterling personal character. He has received many tokens of honour from the Sovereigns whom in peace and war he served, from the university and the college which he helped to govern, and from the profession which he still adorns; he will not, I feel sure, be other than gratified by the tribute of cordial regard which in your name I venture to offer him on his retirement.

After ten years of service, Dr. E. H. Bennett has ceased to represent the University of Dublin in this Council, where his sturdy common sense and firmness of purpose were recognised by all. Those who remember his predecessor will agree that it was no easy task to follow Dr. Samuel Haughton, whose manifold experience and sprightly temper gave him a unique place in our counsels. But it will also be readily admitted that the influence and repute of his university have suffered no detriment at the hands of Dr. Bennett. He was always willing to take his share in the administrative and educational work of the Council, and he did well whatever he undertook.

Sir Victor Horsley, who was first returned as a directly-elected member in 1897, resigned his seat on October 29th, in order that the Council and the medical practitioners of England might be saved the inconvenience of a bye-election next year. But for his forethought and consideration it would have been necessary, under the provisions of the Medical Act, 1886, to hold a bye-election not only in 1907, but in every fifth year thereafter. His resignation at the present time has rendered it possible so to arrange matters that, now and henceforth, a general election of three English members every five years may suffice. The Council and the electors will properly appreciate the fact that Sir Victor has had in mind their interests in thus choosing the date at which he lays down his office. The Council certainly will not soon forget a colleague, who, after attaining high eminence as a physiologist and a surgeon, gave himself enthusiastically to the public service of his fellows, and strenuously laboured to overthrow whatever he deemed to be an obstruction to professional progress. Though we might not all share his opinions on all subjects, we could not fail to be impressed by the alertness of his mind, the acuteness of his criticism, and the zeal of his advocacy.

In place of Sir Patrick Heron Watson, the Royal College of Surgeons of Edinburgh has appointed Mr. Hodsdon, who, both as a surgeon and as a man of affairs, bears a high reputation among his professional brethren in Scotland. In place of Dr. Bennett, we welcome back to the Council an old friend in the person of Sir Charles Ball. His qualities as a colleague we already know and value.

As I have indicated, the place of Sir Victor Horsley will be filled on December 12th, by means of the general election now proceeding. For the three English seats ten candidates have been duly nominated, and for the one Scottish seat two candidates. The present directly-elected members of the Council, Mr. Brown, Mr. Jackson, and Dr. Bruce, are nominated for re-election.

In fulfilment of the wish expressed by the Council in November last, the Executive Committee has obtained the consent of the Privy Council to a modification of the regulations which have hitherto governed the method of voting in such elections. By the use of signed envelopes enclosing unsigned voting-papers, the elector is now enabled to record his vote without disclosing his identity to the enumerators, or to others who may be present during the process of counting. In other words, the method authorised by the new regulations is practically that of voting by ballot, which has long been current in parliamentary and other elections elsewhere. The Executive Committee has to thank Dr. Leonard Kidd and Sir Victor Horsley for suggestions as to practical details, which have been embodied by the Privy Council in the amended schedules.

In two other matters of importance, His Majesty in Council has been pleased to give effect to the representations of the Executive Committee on your behalf.

The petition of the British Optical Association for the grant of a Charter, concerning which resolutions were adopted by the Council on May 24th, and transmitted to the Lord President, has been refused. It is moreover understood that the Sight-testing Opticians Bill introduced in the House of Lords with a purpose similar to that of the proposed Charter has been dropped.

Another petition for a Charter of Incorporation was presented by the "National Association of Medical Herbalists of Great Britain, Limited," and was advertised in the *London Gazette* at the beginning of July. As it was apparent that the grant of the powers and privileges sought for would be dangerous to the public, and would tend to defeat the purposes of the Medical Acts, a memorandum setting forth the objections to the grant was drafted, and approved by the members of the Executive Committee for transmission to the Lord President. We have now been officially informed that in this case also His Majesty in Council has been advised to refuse the prayer of the petitioners.

The Executive Committee has had before it some additional information respecting medical qualifications in Japan other than those conferred by the Imperial University. On this subject it will report in due course to the Council. The committee has also under consideration applications from the Provincial Medical Board of Novia Scotia, and from the University and College by which medical degrees are granted in that province, requesting that in pursuance of the Order in Council of May 11th, 1906, these provincial diplomas may be recognised for registration in the Colonial List of the "Medical Register." A memorandum setting forth the course of medical study and examinations enforced by law in Nova Scotia has been prepared for the information of the committee, and will be printed with its minutes on the subject.

During the summer it was my privilege to revisit Canada, in connection with the meeting of the British Medical Association at Toronto. By the kindness of the Lord President of the Privy Council and of the Governor-General, I was enabled to meet Ministers of the Crown at Ottawa, Toronto, and Quebec, and other influential persons interested in the subject of medical reciprocity between Canada and the Mother Country. I found that in some cases misconceptions existed as to the effect of recent Imperial legislation on the question, and as to the steps that are now necessary to procure the application of the Medical Act of 1886 to particular provinces. There is reason to believe that the explanations offered in answer to inquiries on these points have been serviceable in removing such misconceptions. Indeed, from an unofficial communication that has recently arrived, it would appear that in one important province, which at present does not accept British diplomas for registration, active steps are now being taken to bring about the mutual recognition of medical qualifications as between this country and the province. It gives me great pleasure to acknowledge the courtesy which as your President I received at the hands of the Dominion and provincial Ministers, and of the university and medical authorities, in Canada. From what I was able by their kindness to see and hear of the conditions of medical and scientific education in the Dominion, I was strengthened in my conviction that nothing but good can result from a closer connection and a freer interchange between the professional schools there and here.

The four-hundredth anniversary of the University of Aberdeen was celebrated last September, with unexampled magnificence on the part of the academic and municipal hosts, and with the utmost satisfaction on the part of the guests who had been invited from all parts of the world. As many members of the Council were privileged to be present, I need not enlarge on the intrinsic interest or the perfect organisation of the ceremonies. These ceremonies culminated in the solemn opening, by their Majesties the King and Queen, of the noble buildings added to Marischal College for the better accommodation of the university, and especially of that school of medicine which in the past has so greatly enhanced its fame. I should, however, report that the Address of Congratulation, which you instructed the President and treasurers to present in your name, was very graciously received by the venerable Chancellor, Lord Strathcona and Mount Royal, and that assurances have reached us that the action of the Council herein was highly appreciated by the University of Aberdeen. The text of the address has, in accordance with precedent, been reported to the Executive Committee and entered in its minutes

During the hearing of certain cases in May, the desire was expressed that the Council should be formally notified of all cases in which medical or dental practitioners are convicted on such charges as might bring them within the operation of the penal clauses of the Medical or Dentists Act. Communications were accordingly addressed by the Registrar to the Secretary of State for the Home Department, the Under-Secretary for Scotland, and to the Chief Secretary to the Lord-Lieutenant of Ireland, asking that instructions might be given to this effect. From England and Ireland we have received replies stating that the desired instructions have been issued; from Scotland we have so far heard only that our request "will receive attention."

In certain cases that will come before you for inquiry, information received in consequence of the steps thus taken by the Government authorities will be placed at your disposal. The penal cases which you will have to consider do not, I think, raise any new point of principle; they have been carefully prepared for your inquiry by the help of the reconstituted Penal Cases Committee and of your legal advisers. One of the dental cases illustrates afresh the unsatisfactory state of the law in relation to joint-stock companies which purport to carry on professional practice.

The Bills prepared on the Council's behalf, by means of which it is proposed to remedy in some measure the existing abuses, have been communicated to the Lord President; but, acting on advice which we could not disregard, we have not attempted to submit them for consideration by Parliament during the present autumn session. Next year we may hope to be more successful in urging them on the attention of Parliament.

An important opinion from eminent counsel, bearing on the "privilege" attaching to the documents and evidence submitted in connection with the penal procedure of the Council, has been obtained, and will be submitted to you *in camera*. It may be necessary, in pursuance of the advice thus given, that you should sanction an addition to the Standing Orders relating to judicial inquiries under the Medical and Dentists Acts.

The Standing Orders respecting the inspection and visitation of examinations have been so adjusted by the Executive Committee as to embody the important principles laid down by the Council at its last meeting. You will be asked to approve the form into which the rules have been cast by the committee; and formally to sanction the issue of a revised edition of the Standing Orders, which, owing to the accumulation of a number of minor amendments made from time to time by the Council, it has been thought necessary to prepare.

The important report of the Practical Midwifery Committee has by your direction been forwarded to the several teaching and examining bodies for their observations. From a large number of these bodies replies have been received, and have been arranged by the Registrar for the information of the committee, which met yesterday to consider them. The committee will probably be able to report during the present session on the progress it has made.

The Education Committee also will have something to say on the questions remitted to it on the motion of Dr. Bruce (Minutes, May 26th, 1906), namely, what effect has been given to the proviso concerning pupilage contained in one of the recommendations of the Council, and generally what steps are taken by the licensing bodies to ensure that the fifth year of the minimum curriculum shall be devoted to clinical study. From enquiries which have been made by the Registrar it would appear that little or no use is made of the permission to reckon a period of pupilage with an approved practitioner as part of the fifth year. It will be for the Council to consider whether a proviso that is practically inoperative is worth retaining. Its inclusion among our recommendations has already given rise to misconceptions regarding the lawfulness of employing in medical practice the assistance of unqualified students who are described as pupils.

In conclusion I would say that, so far as can be foreseen, the business on the programme will probably be compassed by the end of this week. As the General Registrar and his staff will soon be immersed in the laborious work of receiving, verifying, and counting ballot-papers, under the direction of the Branch Council for England, the comparative lightness of our agenda is highly convenient on this occasion,

A vote of thanks to the President for his address, with a request to let it be printed in the minutes, was

proposed by Dr. NORMAN MOORE, seconded by Dr. LITTLE, and carried by acc amation.

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and agreed to after a short discussion, that the two following yearly tables, together with the Registrar's report thereon, be received and entered on the minutes :—

1. Table showing results of competition held in July, 1906, for commissions in the Army Medical Service.

2. Table showing results of competition held in July, 1906, for commissions in the Indian Medical Service.

In the report it appeared that there were forty-seven candidates, of whom twenty-five passed for vacancy, nine qualified, but were unsuccessful, and thirteen were rejected.

Moved by Dr. MCVAIL, seconded by Mr. YOUNG, and carried after a slight alteration—*i.e.*, the omission of the last five words—had been proposed as an amendment (which was lost) by Dr. SAUNDBY, seconded by Dr. ADYE CURRAN : " That the thanks of the Council be conveyed to the Director-General of the Army Medical Service and the Under-Secretary of State for India respectively for the returns which they had again furnished to the Council, with the request that these returns may in future continue to be furnished to the General Medical Council.

On the motion of Dr. NORMAN MOORE, seconded by Mr. THOMSON, the following report of the Executive Committee on the dental business transacted since the last meeting of the Council was received and entered on the minutes :—

REPORT.

(1) The prescribed conditions having been duly fulfilled in each case, the names of the undermentioned persons have been restored to the Dentists' Register, from which they had been erased in conformity with the provisions of Section 12 of the Dentists Act, 1878 :

Cameron, David J.	Hall, William H.
Campbell, George.	Harris, Harold O. W.
Dallachy, James W.	Highfield, Henry.
Davies, Bertrand S.	Hooper, Gordon.
Donovan, Frederick.	Mulliner, Thos. C. M.
Forewell, Henry.	Philson, Matthew S.
Gartrell, John H.	Washbourne, Henry A.

(2) Information was received, through the Colonial Office, of the intention not to proceed with a proposed Bill to regulate Dental Practice in the Colony of Hong Kong.

(3) The committee received from the authorities in England and Ireland promises to furnish to the Council records of all fines inflicted on dental practitioners, and an assurance from the Under Secretary for Scotland that the matter would receive attention.

(4) The committee received, through the Colonial Office, a copy of an Act to regulate the Practice of Dentistry in Newfoundland, and referred it to the Dental Education and Examination Committee for its information.

(5) A communication was received from the Royal College of Surgeons of England intimating that its Licence in Dental Surgery had been withdrawn from three dental practitioners whose names had been erased by the General Council at its May session.

DONALD MACALISTER,
November 26th, 1906. Chairman.

Moved by Dr. NORMAN MOORE, seconded by Sir JOHN WILLIAM MOORE, and agreed to, that the report from the Executive Committee as to the Revision of the Standing Orders relating to Visitation and Inspection be received and entered on the minutes

Moved by Dr PYE-SMITH, and seconded by Sir JOHN WILLIAM MOORE, that the report of the Executive Committee be adopted.

An amendment, moved by Dr. LINDSAY STEVEN, seconded by Sir JOHN BATTY TUKE, that in Clauses A2 and B2 the words, " and of the Education Committee acting jointly " be introduced after " Examination Committee," so that both clauses read : " It shall be the duty of the Examination Committee and of the Education Committee acting jointly to advise the Council . . . . . ," was carried, and the Standing Orders as amended were then adopted.

Moved by Dr. NORMAN MOORE, seconded by Mr. THOMSON, and agreed to : That the report as to other adjustments of the Standing Orders be received and entered on the minutes, and that power be given to the Executive Committee to issue the Standing Orders when read.

Moved by Dr. NORMAN MOORE, seconded by Mr. MORRIS, and agreed to : " That the report by the Executive Committee as to the result of the communication with the Privy Council to secure election of direct representatives by ballot be received and entered on the minutes. The report stated that the Privy Council had given its consent.

The Council having deliberated *in camera* on strangers being readmitted, the President announced that the Council had directed the Registrar to restore to the Dentists' Register the name and qualification of William Jones.

The Council then adjourned.

SECOND DAY, WEDNESDAY, NOVEMBER 28TH, 1906.

DR. MACALISTER, President, in the Chair.
Absent—MR. POWER.

The minutes of the last meeting having been read and confirmed, the Council proceeded to the consideration of the case of James William Ayres, registered as of 111, Farnworth Street, Liverpool, L.R.C.S.Edin., 1874, who had been summoned to appear before the Council to answer the following charges as formulated by the Council's solicitor : " That you were, on October 5th, 1905, convicted at the City Police Court, Liverpool, of being drunk in a certain public street in Liverpool, and guilty while drunk of riotous behaviour therein, and also that you were, on December 7th, 1905, convicted at the same Court of wilfully neglecting your children, who were all under the age of sixteen years, in a manner likely to cause them unnecessary suffering."

Mr. AYRES attended to answer his notice, but was not represented by counsel or solicitor. The solicitor of the Council, Mr. Winterbotham (in the absence of a complainant), read the two certificates of conviction set forth in the notice, and at the request of Mr. Ayres also read the letter which Mr. Ayres had sent in answer to his notice. Mr. Ayres then addressed the Council, and also answered questions put to him by the Council's solicitor. When strangers and Mr. Ayres had been re-admitted after the Council had deliberated *in camera*, the president announced the decision of the Council as follows :—Mr. Ayres, I have to inform you that the Council have deliberated very carefully on your case, and have passed the following resolution : "That James William Ayres having been proved to have been convicted of misdemeanour, the Registrar be directed to erase his name from the Medical Register."

The Council proceeded to the consideration of the case of Henry Cundell Juler, registered as of 141, Garfield Place, Cincinnati, Ohio, U.S.A., M.R.C.S., 1853, Lic. Midwif. R.C.S., 1854, M.D.Aber., 1855, L.S.A. Lond., 1856, who had been summoned to appear before the Council in answer to the following charge as formulated by the Council's solicitor :—" That information and evidence have been laid before the Council that you were, on July 10th, 1905, convicted at Marlborough Street Police Court of committing an act in violation of public decency in Hyde Park." Dr. Juler did not answer to his notice, nor was he represented by counsel or solicitor. The Council's solicitor, in the absence of any complaint, read the certificate of conviction, and put in two letters from Dr. Juler in answer to the charge, which were not read, as they were already in possession of the members of the Council. On strangers being re-admitted, after the Council had deliberated *in camera*, the President announced the decision of the Council as follows : " That Henry Cundell Juler having been proved to have

been convicted of a misdemeanour, the Registrar has been directed to erase his name from the Medical Register."

The Council then proceeded to the consideration of the case of Edmund McDonnell, registered as of 25, Hereford Street, Sheffield, L.R.C.P.Edin., 1880, L.R.C.S.Edin., 1886, who had been summoned to appear before the Council to answer the following charges, as formulated by the Council's solicitor:—

"(1) That you have acted as cover to an unqualified person, namely, Mr. William Williams Alnwick, and knowingly enabled him to attend and treat patients and otherwise to engage in medical practice as if the said William Williams Alnwick were a duly qualified and registered medical practitioner.

"(2) That you knowingly allowed the said William Williams Alnwick to fill up and sign in your name a certain certificate of death, namely, that of Ellen Millward, which stated that you had attended the said Ellen Millward in her last illness, and that you had last seen her alive on September 20th, 1906, whereas in fact you had not attended her or seen her, but the said William Williams Alnwick had alone attended and seen her.

"And that in relation thereto you have been guilty of infamous conduct in a professional respect.

"And further, that information and evidence have been laid before the Council that you were, on July 24th, 1906, convicted at the Sheffield City Petty Sessions on three charges of drunkenness, and that you were, on September 13th, 1906, convicted at Belfast of drunkenness."

Mr. McDonnell was called, but did not answer to his notice, nor was he represented by counsel or solicitor. Mr. Winterbotham read the notice, and also a supplementary notice, which he had sent relating to a later conviction for drunkenness. In the absence of any complainant, Mr. Winterbotham proceeded to lay before the Council the information on which the charge had been based. He read letters from the Registrar-General and the Deputy Coroner of Sheffield, together with the certificate of death of Ellen Millward. He also read a report of the evidence given by Mr. McDonnell at the inquest held on Ellen Millward, and the various certificates of Conviction, dated respectively June 5th, 1906, July 13th, 1906, July 24th, 1906 (two), and September 13th, 1906. Mr. Winterbotham read the letter which Mr. McDonnell had written in answer to his notice.

Strangers having been re-admitted after the Council had deliberated *in camera*, the President announced the decision of the Council as follows: "The Council have judged Edmund McDonnell to have been proved to have been convicted of various misdemeanours, and to have been guilty of infamous conduct in a professional respect, and have directed the Registrar to erase from the Medical Register the name of Edmund McDonnell."

The Council next received *in camera* an opinion of Dr. Blake Odgers and Mr. Lushington.

On strangers being re-admitted, Mr. YOUNG moved and Dr. MCVAIL seconded: "That it be remitted to the Students' Practical Midwifery Committee to consider and report as to the inclusion of clinical and practical work in the qualifying examinations in midwifery and gynæcology." This was carried after a short discussion, in which Dr. Finlay, Dr. Bruce, Sir Hugh Beevor, Dr. Norman Moore, Sir John Williams, and Sir Thomas Fraser took part.

Moved by Sir THOMAS MYLES and seconded by Dr. ADYE-CURRAN: "That it be remitted to the Education Committee to consider and report how far it may be possible to dispense with the compulsory attendances of students on the systematic courses of lectures in the theatres of medical schools, in order that the time so saved might be devoted to a more extensive study of the purely scientific portion of the curriculum or utilised in any such manner as may be found hereafter to be demanded by modern requirements." This motion met with considerable opposition from Sir Christopher Nixon, Sir John W. Moore, Dr. Norman Moore, Sir J. Fraser, Dr. Mackey, and Dr. Lindsay Steven. Sir Thomas Myles had made a strong but humorous reply, but the motion was lost—17 against, 7 for, 5 did not vote, 4 absent.

The next motion was proposed by Dr. ADYE-CURRAN and seconded by Dr. LINDSAY STEVEN: "That in consideration of the heavy expense entailed on the Apothecaries Hall, Dublin, by the appointment of the surgical examiners from London and Edinburgh respectively, the Council resolve that at the next vacancy surgical examiners be appointed from amongst the profession practising in Dublin." After a short discussion, Dr. Adye-Curran, with the consent of the Council and of his seconder, withdrew his motion.

The Council then adjourned.

THIRD DAY.—THURSDAY, NOVEMBER 29TH, 1906.

DR. MACALISTER, President, in the Chair.

THE Council considered a Report of the Dental Committee on the charge against Samuel Foley, William Henry Moseley, and James Parkinson. On November 6th, 1906, the two first-named attended in person before the Committee with counsel and solicitor, the last-named not appearing in person but being represented by his solicitor. The complainants, the British Dental Association, were represented by Mr. R. W. Turner.

The Committee found that the following facts were established by the evidence:—

(*a*) The three dentists above-mentioned are all on the "Dentists' Register" as in practice before July 22, 1878, and their addresses in the Register are as follows:

Samuel Foley, 266, Westminster Bridge Road, London, S.E.

William Henry Moseley, 6, St. Matthew's Street, Ipswich.

James Parkinson, 116, Uxbridge Road, Shepherd's Bush, London, W.

(*b*) On or about May 29th, 1899, the three dentists above-mentioned signed the Memorandum and Articles of Association, and thereby became members of a limited company named Foley's, Limited, incorporated under the Companies Acts for the purpose (*inter alia*) of carrying on the "business of dentists and dental surgeons."

(*c*) The company, immediately after its formation, entered into an agreement with an unregistered person named Edward Foley, a brother of the said Samuel Foley, for the acquisition from the former of five dental practices at the following addresses, namely, 75, Westbourne Grove, W.; 21, High Street, Kensington, W.; 95, North End, Croydon; 32, Tavern Street, Ipswich; and 89, King's Road, Brighton. The said unregistered person named Edward Foley was and is the sole and managing director, and also the principal shareholder of the company.

(*d*) The company now carries on practice at all the above-mentioned addresses except the last, and employs the said Edward Foley to attend patients and perform dental operations, and takes and uses the title of "dentists" and "surgeon dentists."

(*e*) The Company advertises systematically and extensively by circulars of an objectionable character and containing claims of superiority over other practitioners.

(*f*) Samuel Foley signed the Memorandum of Association of the company for five founders' shares, and William Henry Moseley and James Parkinson for ten Founders' shares each, but they have never paid anything in respect thereof or received any dividends thereon. The total issued capital of the company is sixty-five founders' shares and two thousand ordinary shares, all of £1 each, of which the said Edward Foley owns five Founders' shares and all the ordinary shares.

(*g*) Samuel Foley, at and previously to the formation of the company, practised at the same address as his brother, the said Edward Foley, namely, at 89, King's

Road, Brighton. He only resided there from Saturday till Monday in each week. He subsequently handed over the premises and the brass plate bearing the inscription, "Mr. Foley, Dentist," and the furniture and appliances to his brother, and ceased to practise there himself.

The said Samuel Foley took no part in the management of the business carried on by the company, and was carrying on a practice himself elsewhere, but he was well aware of the object with which the company was formed, and knew that it was to enable his brother as an unqualified person to advertise himself and carry on practice as a dentist and surgeon dentist.

(*h*) The said William Henry Moseley, at and previously to the formation of the company, and for about three years subsequently thereto, was in the employ of the said Edward Foley, and he signed the Memorandum of Association at the request of the said Edward Foley.

All three now appeared to answer their notices. Mr. S. Foley was accompanied by his counsel, Mr. Courthope-Munroe, Mr. W. H. Moseley by his solicitors, Mr. J. H. Ryley, of Ipswich, and Mr. Priest; and Mr. Parkinson by Mr. R. C. Kerr. The British Dental Association was represented by Mr. R. W. Turner, counsel. Mr. Courthope-Munroe, Mr. Priest, and Mr. Kerr addressed the Council on behalf of their respective clients, and Mr. Turner replied on behalf of the complainants. After the Council had deliberated *in camera*, the parties and strangers were re-admitted, and the President addressed Mr. Foley as follows: "Mr. Foley, I have to announce that on the facts found in the Report of the Dental Committee, in your case, it has been proved that you have been guilty of conduct which is infamous or disgraceful in a professional respect, and the Council directs the Registrar to erase your name from the 'Dentists' Register.'"

The President then addressed Mr. W. H. Moseley and Mr. J. Parkinson as follows: "I have to announce to you that the further consideration of the charge against you has been postponed until the next Session of the Council, when you will be expected to show to the satisfaction of the Council that you have done your best to sever all connection with the company of Foley's, Limited, and that your professional conduct has been in all respects satisfactory in the interval."

The Council next proceeded to the consideration of the report of the Dental Committee on the charge against William Williams Alnwick. On November 28th, 1906, Mr. W. W. Alnwick attended before the Committee and was heard.

The case having been brought to the attention of the Council by the Registrar-General, the facts were laid before the Committee by the solicitor.

The Committee find that the following facts were established by the evidence:—

(*a*) The said William Williams Alnwick is on the "Dentists' Register" as in practice before July 22nd, 1878, and of the address 39, Highfield Place, Sheffield.

(*b*) The said William Williams Alnwick, being a registered dentist, but not being a registered medical practitioner, has attended and prescribed for patients as though he was a duly qualified and registered medical practitioner, and has, in the name of one Edmund McDonnell, a duly registered medical practitioner, signed a death certificate in the case of Ellen Millward, whom the said William Williams Alnwick had so attended and prescribed for.

(*c*) The said William Williams Alnwick has been carrying on a general medical practice for over thirty years.

(*d*) The said Edmund McDonnell has resided for the last eight or nine years with the said William Williams Alnwick, and has been his "assistant partner" in medical practice.

The said William Williams Alnwick was authorised by the said Edmund McDonnell to sign his name to the certificate of death of the said Ellen Millward, although in fact the said William Williams Alnwick alone had attended her, and the said Edmund McDonnell had not attended her.

(*e*) The said William Williams Alnwick was convicted on October 30th, 1906, at the Sheffield City Police Court, of forging the certificate of the death of the said Ellen Millward for the purposes of the Births and Deaths Registration Act, 1874, and was fined £3 14s. and £1 6s. costs.

Mr. Alnwick attended in answer to his notice, and, after the Report had been read, he addressed the Council. Among other things he said he had attended over 2,000 cases of midwifery. After the Council had deliberated *in camera*, when Mr. Alnwick and strangers had been re-admitted, the President announced the decision of the Council as follows: "That William Williams Alnwick having been proved to have been convicted of a misdemeanour, the Registrar, has been directed to erase his name from the 'Dentists' Register.'"

The Council again went into *camera* to receive a Report by the Dental Committee in regard to certain applications for the restoration of names after erasure under Section XIII. of the Dentists Act.

Strangers having been re-admitted, it was moved by Dr. McKay, seconded by Dr. Norman Moore, and agreed to: "That the Report from the Education Committee on the operation of recommendation of the Council in regard to the fifth year of professional study be received and entered on the Minutes."

Moved by Dr. Mackay, seconded by Dr. Norman Moore, and agreed to: "That the following alteration, as recommended in the Report, be made in the Recommendations of the Council: 'That the reference to a period of pupilage' be adopted." Another Recommendation in the Report: "That special reference should be made to instruction of anæsthetics," was adopted, on the motion of Dr. Mackay, seconded by Mr. Morris.

The adoption of a third Recommendation in the Report: "That special reference should be made to attendance at *post-mortem* examinations," was proposed by Dr. Mackay and seconded by Dr. Lindsay, Steven. An amendment, however, was moved by Mr. Young, seconded by Dr. McVail, that the following words be substituted: "To giving attendance at and taking part in, *post-mortem* examinations." After a lengthy discussion, in which Dr. Lindsay Steven, Sir John Moore, Dr. Caton, Mr. Morris, Sir C. Nixon, Dr. Norman Moore, Dr. McVail, Dr. Little, Dr. Saundby and Mr. Brown took part, the closure was carried and the amendment put and lost—20 against, 8 for, 2 did not vote, 3 absent. The original motion was then put and carried.

Moved by Dr. Mackay, seconded by Dr. Lindsay Steven, and carried: "That the Recommendation in the Report, 'That statistics relating to the length of the curriculum actually pursued by students under the present regulations should be procured and laid before the Council,' be adopted."

Sir John Tuke was appointed a Member of the Finance Committee and on the Dental Committee on behalf of the Scottish branch, and Dr. Little on behalf of the Irish branch on the first Committee.

An amendment moved by Dr. Norman Moore, seconded by Dr. Lindsay Steven: "That from the Reports of the Examination Committee the passages referring to the Order of Merit be omitted," to Dr. McVail's motion, seconded by Mr. Young: "That the Reports of the Examination now presented in regard to the result of examinations for the Public Services" be received and entered in the Minutes, was carried, and it was agreed that the Reports thus amended should be received and entered in the Minutes.

The President announced the appointment of Sir T. R. Fraser as a member of the Examination Committee on the nomination of the Scottish Branch Council in the place of Sir P. Heron Watson.

The Council then adjourned.

Fourth Day, Friday, November 30th, 1906.

Dr. MacAlister, President, in the Chair.

Moved by Sir John Tuke, and seconded by Dr. Mackay: That the note to Requirement III. in regard

to Professional Education be deleted and that in its place the following note should be adopted: "That the Council is of opinion that the required subjects should be divided into two groups; one group comprehending Physics, Chemistry, Elementary Biology, Anatomy, and Physiology, the other comprehending all the other subjects; and that the Council is of opinion that no licensing body should recognise instruction in any subject comprehended in the second group until candidates have passed in the subjects comprehended in the first group." Sir T. McCALL ANDERSON, seconded by Sir JOHN MOORE, moved an amendment to the effect that a minimum of two years be devoted to the final examinations, and no qualifying courses be recognised till all the preliminary courses be passed.

A long discussion followed, in which Sir Thomas Fraser, Dr. Caton, Sir C. Nixon, Mr. Morris (who pointed out that the question of treating preliminary scientific subjects apart had been before the Council since 1864), Dr. Norman Moore, Sir John Williams (who, seconded by Dr. Little, moved as rider that the education of the student should be divided into three groups), Dr. Bruce, Dr. Lindsay Steven, Sir Thomas Myles, Dr. Kidd, Mr. Thomson, and Dr. McVail took part. Another rider was proposed by Dr. Kidd, seconded by Dr. Saundby, and eventually the original motion, the amendment and the two riders were referred by vote to the Educational Committee.

Moved by Sir JOHN MOORE, seconded by Sir THOMAS MYLES: That the Governor and Court of the Apothecaries' Hall, Dublin, be requested to furnish for the information of the Council a statement showing in reference to the Final or Qualifying Examination of that body: (1) The number of candidates who have presented themselves for the said examination since the appointment of Examiners in Surgery by the Council; (2) the number of candidates who have been successful at the said examination; (3) the subjects in which the unsuccessful candidates have failed; (4) the numbers rejected in each of the subjects in question.

Mr. BROWN moved as an amendment; seconded by Dr. ADYE-CURRAN: "That the Registrar be requested to afford the information." The motion, as amended, was voted as follows: 12 for, 9 against, 7 did not vote, 5 absent. Mr. THOMSON challenged the motion being carried on this voting as "not being the voting of the majority of the members present."

Moved by Dr. ADYE-CURRAN, and seconded by Dr. SAUNDBY: "That the existing appointments of Assistant Examiners in Surgery at the Apothecaries Hall, Dublin, be terminated next May." This was carried, after some words of praise to the out-going examiners had been added at the suggestion of the President.

Moved by Sir JOHN WILLIAMS, seconded and agreed to: "That the Report from the Students' Practical Midwifery Committee be received and entered on the Minutes."

The PRESIDENT next made a statement on behalf of the Executive Committee in regard to the extension of Part II. of the Medical Act, 1886, to Nova Scotia and to Japan.

Moved by Mr. TOMES, seconded by Mr. MORRIS, and agreed to: "That the Report of the Dental Education and Examination Committee be received and entered on the Minutes." The Recommendation that the Council accede to the request of the University of New Zealand for the recognition of the degree of Bachelor in Dental Surgery was adopted. The same application from the University of Sydney was postponed for further information on the points indicated. The Committee had recommended that the preliminary examination in general knowledge of the College of Dental Surgeons of Quebec be not recognised.

The Report of the Pharmacopœia Committee was received, entered on the minutes, and approved.

Moved by Mr. BROWN and seconded by Mr. JACKSON: "That representations be made to the Privy Council that it is expedient to confer on the Registered Practitioners resident in England and Wales the power of returning an additional member to the General Council." This motion was lost: 12 against, 10 for, 2 did not vote, 9 absent.

Moved by Sir HUGH BEEVOR, seconded by Dr. NORMAN MOORE, and agreed to: "That the Report of the Student's Registration Committee be received and entered on the minutes.

Dr. BRUCE then moved, and Mr. BROWN seconded, a vote of thanks to the Chairman. This motion was carried by acclamation.

FRANCE.

Paris Dec 2nd 1906.

HÆMOPHILIA.

UNDER the name of hæmophilia is recognised a special disposition to hæmorrhages. This disposition is sometimes acquired, but in the immense majority of cases it forms an essential hereditary malady. It can be transmitted from father to son, from grandfather to grandson, passing over a generation. Hæmophilia is rare in girls, boys being almost exclusively affected. In half the cases the affection is not hereditary, but is always congenital.

The geographical distribution of hæmophilia is interesting from the fact that it seems to have a predilection for the northern countries, and especially Germany, England and America. According to Dommartin, who made a study of 100 cases, Germany furnished forty-eight, England eighteen, Switzerland nine, and France eight. The malady is endemic in certain places; it is thus that Vieli found fifteen or twenty hæmophilic families in Rhœzveus, an Alpine village, which he attributed to consanguinity. The Jewish race appears to be particularly predisposed to the malady. The first symptoms of hæmophilia generally show themselves in the first two years of life; after the age of twenty-two all risk disappears.

Hæmophilia is characterised, clinically speaking, by a particular condition of the blood and by three orders of symptoms: external, spontaneous, or traumatic hæmorrhage; insterstitial hæmorrhage (ecchymosis, hæmatoma), and hæmorrhage of the articulations.

Spontaneous hæmorrhage appears as the result of a fit of anger or emotion, or from no apparent cause. It is frequent in spring and autumn, and occurs at night rather than in the daytime. It is generally observed in the form of epistaxis, which is frequently so abundant as to threaten the life of the patient. The gums and mucous membrane of the mouth are also frequently the seat of hæmorrhage, while such accidents as intestinal hæmorrhage, hæmoptysis, menorrhagia, and, above all, hæmaturia, have been observed.

Traumatic hæmorrhage results from the slightest wound or scratch, and is often very grave. According to Grandidier, out of forty-five cases which ended fatally, the hæmorrhage was produced in eleven cases from a slight scratch of the scalp, fourteen from a small break in the skin, or in the mucous membrane of the lips, seven from a bite of the tongue, five from epistaxis provoked by a fall, and in the other cases death by hæmorrhage was caused by an insignificant wound of the foot, the finger, &c. All these cases were purely accidental, but frequently also the hæmorrhage was provoked by a surgical operation. Out of forty cases Grandidier includes avulsion of teeth ten, bleeding six, wet-cupping four, leeches four, circumcision four, section of the umbilical cord eight.

Interstitial hæmorrhage can be observed in the layers of the skin in the form of ecchymosis and petechia, or the blood may follow the sheaths of the muscles,

constituting hæmatoma. When it is spontaneous, the ecchymosis is most frequently on the lower limbs, the tongue and the palate. Traumatic ecchymosis covers a large surface, invading frequently a whole limb. The slightest cause, a pinch, an insignificant knock, is sufficient to provoke it. A patient of Dommartin had an extensive ecchymosis on the gluteal region from sitting on a hard seat.

Hæmatomata occupy particularly the cellular subcutaneous tissue, and the muscular sheaths, especially that of the psoas. It may be spontaneous, or the result of a more or less violent effort. It is accompanied frequently with pain, when it compresses a nerve trunk, sciatic or brachial nerves. The skin covering it is shiny, brilliant and hot, while the temperature sometimes runs high, but in general fever is absent. Hæmatoma rarely suppurates; it is absorbed without leaving any trace.

Hæmophilia or hæmorrhage into the articulations has been particularly studied by Dubois and König. It can be produced by traumatism, but is generally spontaneous. It is observed principally at the large joints (knees, elbows, ankles, hips, shoulders). König recognises three periods in this accident: the first consists of effusion of blood into the articulation, accompanied with fever (repeating hæmarthrosis).

In the second period, the synovial membrane and the cartilages become affected; the joint is swollen, but there is no local temperature, nor has suppuration ever been observed. The neighbouring muscles become atrophied, as in the case of infectious arthritis.

If the blood is not absorbed, the third period sets in, which is that of ankylosis. A frequent error is in the confusion of this curious affection with white swelling, and can only be avoided by closely interrogating the patient on his previous history.

The prognosis of hæmophilia is always very sombre. According to Litten, 60 per cent, of the patients die before eight years of age, while only 12 per cent. live over twenty-two years of age.

The treatment of hæmophilia is limited and unsatisfactory. Reverdin recommended sulphate of soda in small doses (2 grains every two hours), and acidulated drinks. A prolonged use of chloride of calcium or of the dried extract of pig's liver is about the best preventive treatment.

In the treatment of the hæmorrhage itself absolute rest should be imposed on the patient, and chloride of calcium (1 drachm daily) be ordered. Where it is external (epistaxis or cutaneous hæmorrhage following a wound), compression should be applied, and in obstinate cases a local application of a solution of adrenalin (1 in 10,000) is very successful.

Where the patient has fallen into profound anæmia, an injection of artificial serum might be tried. But here, again, the small wound might give rise to another hæmorrhage, consequently, the injection should not be made unless the life of the patient is in danger.

The treatment of arthritic hæmophilia consists in compression and the fixing of the joint in a good position.

GERMANY.

Berlin, Dec. 2nd, 1906

At the Society for Innere Medizin, Hr. Katzenstein made observations on

• The Influence of Gastroenterostomy on Ulcer and Carcinoma of the Stomach.

After observing that very little had been done in this direction beyond the examination of test breakfasts, which often gave negative results, he proceeded to state that his investigation had included examination of animals both before and after gastroenterostomy, and after various articles of food. He had ascertained (1) that after gastroenterostomy of any kind both pancreatic juice and bile passed freely into the stomach. (2) This inflow of alkaline fluid into the stomach was continuous in the early period after the gastroenterostomy—probably through a reflex process founded on the steady secretion of these fluids—but later on the inflow was periodical only. (3) Some months after the operation, after feeding with flesh alone, the pancreatic ferments and bile were demonstrable in the stomach about 1½ hours after taking food; when fat was given, or water, they were found there in half an hour. From this the speaker concluded that both fats and water have the property of exciting when in the stomach the secretion of these fluids by a reflex route, as the reflex could not be excited from the duodenum, that having been shut off from the stomach artificially. This was confirmed in the case of a patient who had had gastroenterostomy performed for carcinoma of the pylorus, and who was given a trial breakfast of fat. (4) The consequences of the inflow of alkaline intestinal juices into the stomach were: diminution of acidity and of pepsine digestion, as pepsine was rendered inactive by even a transitory neutral or alkaline reaction. This lowering of the acidity was caused not only by the actual neutralisation of the acid by the alkali, but also by a reflex lessening of acid secretion. There was also slight weakening of the action of the pancreatic ferments. The ferments, as was shown by the speaker's experiments, were not rendered inactive by a transient acid reaction, as had been assumed. The action of the trypsine began again when the reaction again became neutral; the weakening being dependent on the duration of the acid reaction; but after even twenty-four hours the trypsine action was demonstrable as soon as an alkaline reaction was re-established. This resisting power of the pancreatic ferments was an indispensable condition of efficient nutrition after gastroenterostomy.

He was of opinion that one of the factors for the origination of a gastric ulcer was hydrochloric acid, and that it was the chief factor for its persistence. With gastroenterostomy, therefore, according to his views, a mode of causal treatment was put into action as the production of hydrochloric acid was diminished by it.

The arrest of growth of carcinoma of the pylorus, often observed after the operation of gastroenterostomy, was due, in the speaker's opinion, to a superficial digestion of the tumour by trypsine. For this reason he would extend the indication for gastroenterostomy to every no longer resectionable carcinoma. As regarded ulcer, the indication should stand as before, and gastroenterostomy should be performed only after the failure of all other forms of treatment.

Hr. Ewald had never seen any action of the pancreatic juice on carcinoma. The result of gastroenterostomy on dogs would not necessarily be similar to those on the human subject, as the posture in the dog facilitated the passing of intestinal juices into the stomach, whilst the erect posture of the human subject would make it difficult. In the human subject the inflow in question depended on inefficient function. The results of gastroenterostomy were not always brilliant even in ulcer, as the symptoms sometimes returned after even repeated operations. Amongst the public there were two groups of people, the one would not be operated on at all, and the other not half early enough. The dangers of the operation were much under-estimated. He had seen not a few deaths in carcinoma of the stomach after gastroenterostomy, and as a direct consequence of the operation and especially from collapse.

Hr. Rosenheim had only operated in ulcer of the stomach when there was motor insufficiency and bleeding that threatened life that could not be arrested. The operation results after other indications were not encouraging. He had not seen any diminution in acidity after gastroenterostomy, although he had carefully looked for it for years. He would not extend the indication for operation in gastric ulcer. In regard to carcinoma, he was still more sceptical; he had never seen life prolonged by operation for carcinoma of the pylorus. What happened to those operated on? (1) The symptoms might return; (2) unfavourable conditions as regarded nutrition arose, often stasis in the small intestine; (3) not infrequently ulcer of the jejunum came on, with results that threatened life. (Discussion adjourned.)

At the Medical Society, Hr. L. Lewin brought for-

ward a new remedy for cardiac diseases in the shape of a preparation from the

ACOCANTHERA SCHIMPERI.

For many years he has been studying arrow poison as employed by African natives, which had, as has long been known, an enormous influence on the heart. He had at last succeeded in preparing a glucoside which chemically and toxicologically resembled chrystalline ouabine, except that it was amorphous. He had therefore given it the name of amorphous ouabine. It was found in the wood of the Acocanthera Schimperi, which was widely distributed over the whole of East Africa, and is the most important source of arrow poisons. Ouabine slowed the pulse, strengthened the systole, and with this raised the blood pressure.

AUSTRIA.

Vienna, Dec. 2nd, 1906.

MAXILLARY DEFORMITY.

LORENCZ showed a young girl, æt. 10, who suffered from congenital malformation in the upper maxillary. Cleft palate, hare lip, with a fissure up the centre, were ingeniously closed, leaving the face perfect without a scar.

XANTHOMA TUBEROSUM.

Spiegler showed a case of xanthoma tuberosum in a man, æt. 39, where there were neither glycosuria or hepatic disease, which are considered by some necessary diagnostic signs.

RÖNTGEN PHOTOS OF THE CRANIUM.

Benedikt showed a few photos of cranium and morbid changes in cerebrum from three cases in hospital, all caused by falls. Strange to say all the cases had the lesion in the frontal lobes, although the manner of the fall differed in all the three cases. All of them lost the power of standing erect, and in the effort would fall to one side or the other on the floor. This centre of disturbance is not yet explained, and seems to be erratic in its development. We cannot even determine whether the lesion is cortical or subcortical, as it lies in front of the so-called psychomotor zone.

In the first case, the rays showed the frontal sinuses in one side enormously increased in bony growth closing the connection. Later this bony increase invaded the opposite sinus, becoming dense and opaque. This eburnation extended to both sides of the cranium, and could have no connection with pregnancy or syphilis. The use of iodide and mercury reduced the attacks, and the patient slightly improved.

As a rule the outer lamella of the cranium is as transparent as the inner, but in injuries to the head the outer lamella becomes more opaque than the inner, which seems to be of pathological importance in the diagnosis. Another point to be noted is the peculiar bands to be found in the substantia spongiosa. To illustrate this he showed a plate taken from a man who had his head injured when he was twelve years of age in the parietal region. In this photo distinct bands are seen in the spongiosa of the frontal and parietal bones. A second photo where the disturbance had been in the frontal bones showed distinct spongiosa bands with osseous thickening and a dark centre in front of the psycho motor region, which was probably the centre of disturbance. A third plate showed a depression on the frontal side of the frontenelle, which also clearly showed the bands in the spongiosa of frontal bone.

A few plates from the occipital region showed neoplasms in the cerebellum, which were afterwards dissected in the *post-mortem* room, and found to be soft tumours.

In conclusion, he said that the technical failures in the plates taken by the rays lay in the differentiation of exudations, abscesses and neoplasms of the brain substance.

In the discussion that followed, Schuller remarked that Benedikt's diagnosis should be carefully borne in mind, but according to his own experience the Röntgen rays were only useful in a very limited group of cases, such as injury to the cranium, foreign bodies, or projectiles. They might also be employed for examining fissures, impressions, and depressions of the cranium, also in destructive processes such as hyper-ostosis, local and diffuse. Grossmann thought them useful in the diagnosis of rhinology.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

MEDICAL MAN AS CONVENER OF THE EDINBURGH PUBLIC HEALTH COMMITTEE.—Dr. Matheson Cullen, who has for a number of years done excellent work on the Town Council, and as a member of this Committee, has now deservedly been elected its convener, in place of Mr. Gilson, who has been made Lord Provost.

SEAFORTH SANATORIUM FOR CONSUMPTION.—This sanatorium, which will accommodate twelve patients, and is the first institution of its kind in the United Kingdom to be erected, equipped, and endowed for the free treatment of patients by private munificence, had its foundation stone laid on November 27th by Mrs. Stewart Mackenzie, of Seaforth, to the generosity of whose husband the County of Ross-shire owes the new undertaking. The buildings, which will consist of two blocks, are being erected on the Seaforth estate, about two miles from Dingwall. Each patient will have a separate room, and on the south side of the building large sliding glazed screens open on to a broad terrace 200 feet long, on to which the beds and couches can be pushed when desired. The site has been selected with special care; it slopes to the south, and is sheltered on the north by pine woods. During the ceremony Colonel Stewart Mackenzie emphasised the two-fold object of the sanatorium—first, to cure cases of early phthisis, and second, to educate the people in the value of fresh air as a preventive measure.

PREVENTION OF CONSUMPTION IN GLASGOW.—The annual report of the local branch of the National Association for the Prevention of Consumption states that since their last report the important step has been taken of opening a dispensary where special advice and treatment may be received. The dispensary is under the care of Dr. James Scott, and is already proving a valuable agency both in selecting suitable cases for the Bellefield Sanatorium, and in treating severe and acute cases. The report goes on to draw attention to the fact that so many patients, when they fail to be admitted to the sanatorium, cease attending the dispensary. It would, therefore, be a great advantage to the community if a home or hospital could be provided in the city for advanced cases, so that these should not be compelled to live on in crowded, airless houses. During the year 95 patients have been admitted to Bellefield sanatorium, of whom 40 are reported as having had the disease arrested, 36 as improved, 12 not improved, and two dead. Plans have been prepared for the erection of another pavilion accommodating 22 patients. The report was adopted at the annual meeting held on the 27th inst., when the Lord Provost, who presided, spoke particularly of the steps which were being taken to provide suitable employment for patients after they had left the sanatorium.

BELFAST

THE IRISH UNIVERSITY QUESTION.—The problem of the Irish University Education is being widely discussed at present in medical and professional circles generally in the North of Ireland. This is partly owing to the way in which it was brought forward by Professor Schafer, of Edinburgh, in his speech at the annual dinner of the Ulster Medical Society, as reported in this column a fortnight ago, and partly to the fresh impetus towards a solution given by Mr. O'Brien's generous offer to Cork. A few years ago the number of medical men in Belfast who openly advocated an Ulster University could have been counted on the fingers of one hand—and probably a few fingers could have been spared—but a considerable change

has developed of late, and is still making progress. The two stock arguments against an Ulster University have been that it would be a Presbyterian University, under clerical domination, and that its degrees would be unknown and consequently worthless. But, however much the General Assembly of the Presbyterian Church may wish to control higher education in Ulster, and it is only fair to say that there is no evidence of such a wish on the part of that body, the ordinary Ulster layman is about as little likely to submit to such domination as any man in the world. And as regards the second objection? Belfast is a commercial city, and men know enough of commerce to realise that though an old-established trade-mark may be an excellent asset in a business, a young firm who show enterprise and turn out a good article will soon command a market. Taking too low an estimate of his own abilities is not generally the most prominent failing of an Ulsterman, and there is no doubt that the changes at Queen's College brought about by the Better Equipment Fund have convinced many men that there is a great future in store for the Northern school. That such future will be best attained by an independent school working out its own fate in conformity with local needs and the genius of the province is the opinion of an increasing number of northern graduates.

LETTERS TO THE EDITOR.

THE ELECTION OF THE GENERAL MEDICAL COUNCIL.

To the Editor of The Medical Press and Circular

Sir,—In my note on the election of the General Council (Medical Press and Circular, November 14th) I was careful not to advocate any particular candidate, but having been asked to do so I could not, of course, do more than compare the candidates' addresses with the principles I laid down.

In the first place, Dr. Langley Browne goes out. He advocates taxation—that the profession should pay the Government £37,000 per annum. The omission of this name carries with it the other so-called Association candidates—McManus and Latimer.

Next, there is a general feeling that a clean sweep of all the former members should be made, but this is certainly not universally held, and it is possible that one or both will be returned.

For the Midlands and the North of England, there is no one of the position and authority of Dr. Broadbent, who is, morever, one of those conversant with provident dispensaries.

One principle I did not lay down, namely, the desirability of sending young men to the Council. The conditions of social life are so rapidly changing that the alert mind as well as the wise restraint is needed. The Benjamin of the candidates, qualified in 1885, Dr. Fred J. Smith, is certainly worthy of the honour. Being a university man, he would probably be able to influence the professors, and of Oxford, he would look after the Philistine president, who is of Cambridge.

Dr. Joseph Smith will be supported by a good many "college" men. Of course, my outlook is but that of a London resident. There are currents in the country of which we have little knowledge, and if in the division of votes either or both the other country practitioners are elected, I myself will applaud.

I am, Sir, yours truly,
G. Crichton.

114, Lexham Gardens, Kensington, W.,
November 30th, 1906.

To the Editor of The Medical Press and Circular.

Sir,—It may be thought by some that it is too late publishing any further letters on this election, as Friday next is the last day for voting papers to be received; but I venture to point out that there are perhaps half the number of papers which have not been sent in, therefore, if the readers of the Medical Press and Circular will bestir themselves, and send their copies of it to friends, many votes may be obtained, and although my sympathies are with Dr. Broadbent as the most suitable candidate for furthering and protecting the interests of general practitioners, what I desire above all things is that we should endeavour to rouse interest in the election, and to obtain a large poll.

I am, Sir, yours truly,
H. T. Wylde.

Manchester, December 1st, 1906.

To the Editor of the Medical Press and Circular.

Sir,—The letter of "An Elector" under the above heading in the Medical Press and Circular of the 28th ult. has touched upon a subject of great moment to many general practitioners in London, especially those in proximity with Provident Dispensaries.

How can men be expected to make a decent livelihood when members are received into these dispensaries who pay rentals of £35 a year, with, of course, rates in proportion?

I will only ask the courtesy of space in your next issue to say that I am glad to see that there is at least one candidate in this election who is determined to make a stand on the question of "Contract Practice" in general, and Provident Dispensaries in particular, to the latter of which he has given special attention in opposing them for many years. I allude to Dr. G. H. Broadbent, of Manchester, who is a tried man, and whom, I believe, we can trust as a thoroughly sound and sympathetic representative. I, therefore, hope those who have not yet sent in their voting papers will do so at once, and vote only for him, and so practically give him three votes.

I am, Sir, yours truly,
M. S. Hadford.

192, Wandsworth Road, London, S.W.,
December 1st, 1906.

OBITUARY.

GEORGE BAGOT FERGUSON, M.A., M.D., F.R.C.S.

We regret to announce the tragic death of Dr. G. B. Ferguson, of Cheltenham. In the evening of November 28th, Dr. Ferguson was operating on a patient at the Cheltenham Hospital when he was taken suddenly ill and died almost instantly. Dr. Ferguson was one of the best known and most highly respected general practitioners in the provinces. As an Oxford man in his young days he greatly distinguished himself, taking a First Class in his final Honours Schools before entering at St. Bartholomew's. After serving as house-surgeon to that institution, he went to practise at Cheltenham, and owing to his high attainments and remarkable energy he soon achieved marked success. In 1875, he graduated M.D. of Oxford, having taken his M.B. four years previously, but his partiality for surgery showed itself as years went on, and as late as 1902 he took the F.R.C.S. of England, and in 1903 the degree of Master of Surgery at Oxford. He was always interested in the prevention of disease, and made several useful contributions to the literature of their subject, especially "The Bacteria and their Allies" in 1884, and "History, Nature, and Prevention of Cholera" in 1885. He also wrote a number of papers, principally on surgical subjects, in St. Bartholomew's Hospital Reports. When the British Medical Association visited Cheltenham in 1901, he was elected President, and those who were present at the meeting well remember the charming address he gave on "Scientific Research," and the "go" he put into the work of his office. Lately, for some little time, he had had trouble with his heart, but he never gave up work. It is pathetic, in the light of recent circumstances, to recall the last words of his Presidential address,

"There is no death! What seems so is transition.
This life of mortal breath
Is but a suburb of the life Elysian
Whose portals we call Death."

MEDICAL NEWS IN BRIEF.

Irish Medical Schools and Graduates' Association Dinner.

A HIGHLY successful dinner and entertainment was given at the Hotel Great Central by the Irish Medical Schools and Graduates' Association on November 20th. This Association is alone among the social medical organisations in the Metropolis in admitting ladies to its entertainments, and so much do the members appreciate the privilege that last Wednesday night quite half of those present were of the more desirable sex. Indeed, if the Irish Graduates' dinner were remarkable for nothing else, it was certainly noteworthy in that it attracted a bevy of ladies who for beauty and vivacity could safely hold their own in any assembly in London. To meet them and the members of the Association came many distinguished guests, Admiral of the Fleet Sir Edward Seymour, G.C.B., O.M., the guest of the evening, Sir Dyce Duckworth, Sir Kendal Franks, Dr. Pye-Smith, Mr. Mayo Robson, Dr. McVail, and other well-known people. The Chairman of the Council, Dr. Irwin Scott, presided, and he was supported by Director-General Sir Alfred Keogh, Inspector-General Lloyd, Sir Lambert Ormsby, Sir John Moore, Surgeon-Lieutenant-Colonel Moorhead, Dr. James Stewart, Mr. Charles Ryall, Dr. Macnaughton Jones, and Mr. Canny Ryall (secretary). To the last-named the greatest credit is due for the excellence of the organisation of the dinner, which, together with the entertainment that followed it, bore striking testimony to the skill and foresight with which the arrangements had been made. Besides the cheering influence diffused by the presence of ladies, the dinner gained by the absence of the depressing influence of long-winded and unnecessary speeches. Beyond the customary loyal toasts, "Our Guests," succinctly proposed by Sir Alfred Keogh, and appositely replied to by Sir Edward Seymour and Dr. James Stewart, provided the only occasion for speech-making. After business came pleasure, and the members of the Association and their guests were subsequently entertained by an excellent series of "turns" given by artists of various talents. A show of "Live Marionettes," in which the performer arranged that his own head should surmount the marionette's body, provoked great merriment; it was a clever idea cleverly carried out, and proved quite a feature of the evening. But the whole went with a "click" from start to finish, and it is difficult to say which were the better pleased —the hosts with their guests' enjoyment, or the guests with their hosts' hospitality.

Premium on Baby Rearing.

FOLLOWING the successful example set by the ex-Mayor of Huddersfield, it is announced that the Mayor of Marylebone, London (Sir Thomas Brooke-Hitching) will, with a view to diminishing a high infantile mortality rate in the poorer parts of the borough, present the mother of each child born in Marylebone with £1 on its becoming a year old. The gift will be limited to poor parents in the receipt of less than £2 per week. It is hoped that this may prove an incentive to increased care and attention in the rearing of infants. At the same time, efforts are to be made of an advisory character in the best methods of nurture and treatment in necessary cases. The mayoress will take an active part in the good work.

Metropolitan Hospital Sunday Fund.

THE LORD MAYOR presided at a meeting last week in connection with the Sunday Hospital Fund at the Mansion House, at which the Hon. Sidney Holland, one of the executors of the late George Herring, stated that the fund would benefit to the extent of £600,000 from the estate. He added that £60,000 had been bequeathed to the "Back to the Land" scheme of the Salvation Army, in addition to £40,000 already given; but if that scheme did not prove successful the £60,000 would come into their fund. A vote of condolence was passed with the relatives of the deceased gentleman, and it was decided to place the marble bust of the late Mr. Herring, which was now at the deceased gentleman's house, in the Mansion House. Archdeacon Sinclair presented the financial statement, which showed that £63,000 was collected this year.

The Local Government Board and Alcohol.

THE auditor having criticised the large expenditure on alcohol in one of the districts of the Epping Union, Essex, caused by a medical officer regularly ordering wine or spirits as a medical comfort to aged people in receipt of out-relief, the Epping Guardians asked the Local Government Board to define their powers in the matter. At a guardians' meeting recently a letter was read from the Local Government Board stating that the medical officer's order was legally only an expression of opinion, and, therefore, the guardians could, if they chose, refuse to supply alcohol. It was decided that alcohol be only supplied in urgent cases in future, and that the medical officer ordering it must give a medical reason for so doing.

Hospital Accommodation for Consumptive Patients.

A CONFERENCE of Middlesex councils was held at the Guildhall, Westminster, last week, to consider a proposal made at the general meeting of the Middlesex District Councils' Association, that the local authorities in the county should combine for the purpose of providing hospital accommodation for persons suffering from consumption. Mr. A. W. W. King (Acton), the chairman of the association, who presided, said that he was sure that anything they could do as public health authorities, within their means, they would be happy to do, and what they wanted to find out was the best way to tackle the problem. They had the power of spending the ratepayers' money to try to counteract the effects of the disease, but at the same time had to consider questions of finance, and that made it difficult to take the necessary steps unless the cost was kept down as much as possible. Colonel Gerard Clark, the hon. secretary of the proposed Middlesex Open Air Sanatorium, gave an address. What they wanted, he said, was the simplest possible buildings, with the patients' accommodation so permeated with fresh air that the bacillus could not live in it, and, above all things, it was of vital importance that the establishment should partake of the nature of a labour colony, and that the weekly cost should be as moderate as possible, in order that the poor might be able to have the freest possible recourse to it. He said it was estimated that the capital cost of furnishing the house and providing everything to deal with 50 patients at a time, would be £2,500, which sum might possibly be provided by private persons. The rent of the house would be about £160 a year, and the full maintenance charges would not be more than 25s. a bed per week, a total cost annually of about £3,500. He felt it was so necessary to make a beginning that, although the taking of a house with about two-and-a-half acres of ground was by no means an ideal scheme, it would start the movement, which could, later on, be further developed. The 50 beds would only deal with about 100 patients a year, but at the present time that would be a step in the right direction. In general discussion some doubts were expressed as to the probability of getting consumptives to go to the sanatorium, and the question of compulsory notification was discussed. Mr. King gave some particulars of the action taken by the Acton Council, who had arranged terms with the Mount Vernon Hospital Committee, by which they had

the use of three beds at their hospital for consumptive persons. This arrangement had been in operation for 18 months, and, so far as it went, was fairly satisfactory. The difficulty was to get hold of cases of pulmonary consumption in their early stages. It was decided to form a sub-committee to obtain information as to action (if any) taken by various districts, to communicate with the Mount Vernon Hospital authorities, and prepare and circulate full reports to be considered at an adjourned meeting of the association.

The Brighton Quack Case.—A Judge's Comments.

Before Mr. Justice Lawrance, at Sussex Assizes, on Monday, William Henry Hawkins and his son, William George Hawkins, of Kemp Town, Brighton, were indicted for obtaining money by false pretences by selling powders at Brighton. The father pleaded "Guilty," and the case against the son was withdrawn. Mr. Avory, K.C., who prosecuted, said the powders were extensively advertised as being a cure for all manner of ailments. On analysis they were found to be harmless, but were absolutely useless for any of the purposes for which they were advertised. They consisted merely of a mixture of carbonate of soda and bromide of potassium, which might possibly have done some little good to anybody suffering from indigestion. Accused advertised in the name of clergymen who were supposed to have derived benefit from the use of the powder.—The judge, in passing sentence of three months' hard labour, remarked that the prisoner pretended that two persons, whom he described as clergymen, had been to some part of Africa and learnt the secret of this remedy. He wished the Crown success in undertaking prosecutions of this kind, as it was most desirable, in the public interest, that such frauds should be brought to light and put a stop to.

Catholic University School of Medicine.

At a meeting of the Governing Body of the Catholic University School of Medicine held on November 30th, 1906, it was moved by Dr. R. F. Tobin, and seconded by the Rev. J. Darlington, S.J.:—"That the Governing Body desire to leave on record an appreciation of the greatness of the loss sustained by the Medical School, and by Catholic education in Ireland, in the recent demise of the Rector of the Catholic University, the Right Rev. Monsignor Molloy, D.Sc., whose latest act was so generous a benefaction to the laboratories and general equipment of the school. In addition to their regret at the calamity which has befallen the Medical School, the Governing Body desire to express their profound sorrow at the loss of one who was to one and all a close personal friend."

The Amalgamation of the London Medical Societies.

At a meeting of the Clinical Society of London held on November 23rd, Dr. Hale White proposed, Dr. Frederick Taylor seconded, the following resolution, was was carried *nem. con.*:—"That the Council's advice to the Society to join the proposed Union of Medical Societies be adopted." At a joint special general meeting of the Fellows of the Obstetrical Society of London and of the British Gynæcological Society, held at 20, Hanover Square, W., on November 21st, Dr. F. H. Champneys in the chair, the draft report of the Representatives of the Council of the Obstetrical and of the Gynæcological Societies on the amalgamation question, already passed by the two Councils, having been circulated, the following resolution was put from the chair, and carried unanimously:—"That this Joint Special General Meeting of the Fellows of the Obstetrical and of the British Gynæcological Societies agrees to the scheme of amalgamation adopted by the two Councils, and authorises the honorary secretaries to communicate this decision to the honorary secretaries of the Union of Medical Societies, and to notify them that Dr. Champneys has been appointed the Representative of the Obstetrical Society, and Dr. Macnaughton Jones that of the British Gynæcological Society, to serve on the new Committee." A general meeting of the Pathological Society of London was held on Tuesday, December 4th, at 8.30 p.m., in order that the final opinion of the members upon the incorporation of the Pathological Society in the new Royal Academy of Medicine may be ascertained.

A Surgical Cause Celebre.

The action against Mr. J. Lynn Thomas, F.R.C.S., Surgeon to the Cardiff Infirmary, and Mr. Henry E. Skyrme, M.R.C.S., in general practice at Cardiff, which has been brought by a mining engineer, named Southern, to recover damages for alleged negligent treatment by the defendants whereby he lost the use of his arm after an accident, has been proceeding before Mr. Justice Bigham and a special jury for several days, and had not concluded at the time of going to press, so that we are unable to comment on the case. Several eminent surgeons have been called on both sides, including Mr. William Rose, Emeritus Professor of Surgery in King's College, London, Sir Frederic Treves, Mr. Anthony Bowlby, Surgeon to the King's Household, Sir William Bennett, F.R.C.S., Mr. Edmund Owen, F.R.C.S., Sir Thomas Smith, F.R.S., Mr. Waterhouse, F.R.C.S., Mr. H. W. Page, F.R.C.S., Mr. C. W. M. Moullin, F.R.C.S., with the usual affirmative and non-affirmative opinions, which will doubtless be seized upon as an excuse for another onslaught on the differences that exist in professional opinions.

Westminster Hospital.

A quarterly court of governors was held at Westminster Hospital last week, when Sir John Wolfe Barry, a vice-president of the hospital and chairman of the house committee, occupied the chair. A report was presented by the finance committee calling attention to the present financial position of the hospital, which is most serious. Notwithstanding the fact that the expenditure during the current year has been diminished by nearly £1,000, it has been found necessary to borrow the sum of £5,600 from the bankers in order to meet the ordinary expenses of the hospital, and the governors recognise that a strenuous effort must be made to relieve the intolerable strain caused by the present inadequate support. It was announced that the Lord Chancellor had kindly consented to take the chair at a festival dinner, to be held in April next year, with a view to placing before the public the undoubted claims of this the oldest voluntary hospital in London.

A Catheter Difficulty Overcome.

The minor difficulties that attend the preservation of asepsis are so baffling in practice that it is a temptation sometimes to deviate from the strict course. One such difficulty is that of lubricating catheters. After careful boiling, the catheter is apt to be dipped in the traditional oil, which undoes most of the good of the boiling. Messrs. Reitmeyer and Co. have just introduced a preparation from Germany to meet this difficulty. It is called Catheterpurin, and is composed of glycerine with some gum tragacanth and oxycyanate of mercury. Being put up in collapsible tubes, the required quantity can be squeezed on to the catheter without coming in contact with any vessel or other source of contamination. It seems to answer the purpose of an antiseptic lubricant well.

Trinity College, Dublin.

The following candidates passed the final in midwifery, during Michaelmas, 1906:—William Pearson (passed on high marks), Malcolm K. Acheson, Richard G. S. Gregg, Robert E. Wright, George G. Vickery, Henry I. Keane, William S. Tracker, Archibald L. Robinson, Edward C. Stoney, John W. Lane, Frederick Stevenson, John H. Morton, John A. L. Hahn, James C. C. Hogan, Ernest T. Jameson, Langford V. Hunt, Joseph C. A. Ridgway, and Henry P. Hart. The following passed the final in surgery:—John du P. Langrishe (passed on high marks), Thomas O. Graham, Cecil T. Conyngham, Richard Connell, Malcolm K. Acheson, Langford V. Hunt, Francis Casement, Francis O'B. Ellison, William Hutcheson, Theodore C. Somerville, Michael P. Leahy, Percy B. Egan, Henry B. Leech, John H. Waterhouse, Herbert J. Wright, George T. Walton, Dudley F. Torrens, and Charles G. Sherlock.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT MEDICAL LITERATURE.

Action of Sunlight on Milk (*Berlin. Klin. Woch.*, 1906).—Much and Romer announce that the results of their tests have demonstrated that sunlight and oxygen alter the taste of milk after even a brief exposure. They affect the fat in the milk, altering it to a kind of tallowy consistency from oxidation of the fat. Milk thus altered is liable to affect infants injuriously. They advise that milk bottles should be wrapped in black, red, or green paper. The same effects are observed after exposure to sunlight with their perhydrase milk as with ordinary raw milk. Their aseptic perhydrase milk is prepared by treating ordinary milk with peroxide of hydrogen, which sterilises it completely. The peroxide of hydrogen is then eliminated with a "catalase" derived from beef cattle. Milk thus treated seems to keep indefinitely, they state, even without ice. D.

Length of Survival after Onset of Tuberculosis (*Norsk Mag. f. Laeg. Christiana*, 1906).—A committee has been diligently at work since 1904 collecting data in regard to the after-history of persons known to have pulmonary tuberculosis in Norway. Blank circulars were sent to physicians, and reports were received in return of 2,005 cases of pulmonary tuberculosis—905 men and 1,100 women. They show, amongst other points, that out of 2,002 tuberculous patients whose history was traced for four years, 1,094 had died, and 908 were still living, of whom 52.3 per cent. were still able to keep at work. Out of 1,658 whose history was traced for nine years, 1,336 had died by the end of this time, and 322 were still alive, with 67.4 per cent. still able to work. The committee calls special attention to the surprisingly large proportion of the tuberculous with comparatively unimpaired earning capacity after four years. The data further show that the average survival after symptoms of tuberculosis were first observed ranged from 36 to 59 months. D.

Paroxysmal Tachycardia.—Reinhold (*Zeit. f. Klin. Med. Berlin*) reviews the recent literature on the relations between paroxysmal tachycardia and affections of the nervous system, and describes two cases. In one the tachycardia was due to a syphilitic basilar meningitis; in the second to a tumour in the left half of the brain. The findings in the heart were entirely negative in each case. D.

Polycythæmia with Enlarged Spleen.—Bence (*Deut. Med. Woch.*, Berlin and Leipzig, 1906) reports three cases in detail. He treated the patients with repeated venesection, and each time the general condition showed marked improvement; the congestion and headache were relieved. Inhalation of oxygen had a similar effect. He administered daily from 50 to 100 litres of oxygen, after which the patients always felt much better, losing their dizziness. The chief disturbances experienced by the patient are due to the over-filling of the vessels from the extreme viscosity of the blood. In the case of a patient with 7,400,000 reds, six days of oxygen inhalation reduced the number to 6,000,000. The inhalations were kept up for three months, and by the end of a year the number was 4,800,000. In one case Bence restricted the patient to a fluid diet, with good results. D.

The Nucleus Test in Pancreatic Disease.—Dutton Steele (*Univ. of Pen. Med. Bull.*, Nov., 1906) has been investigating Schmidt's test in the diagnosis of pancreatic disease. Schmidt and Wallenfang demonstrated in artificial digestion outside the body that the cell nuclei of muscle are digested by the pancreatic secretion alone, and not by the other digestive ferments. Small balls of meat about the size of a pea were wrapped in a bag of net, hardened in alcohol, and given to the patient. These were recovered from the stools in about 18 hours, a purgative being given if necessary. They were then sectioned and examined microscopically. Schmidt investigated four cases of pancreatic disease, two with complete occlusion of pancreatic duct and destruction of the gland, and two with incomplete closure. In the former cases the nuclei were undigested, in the latter completely digested. In 100 cases of healthy persons and patients with gastro-intestinal disease other than pancreatic, the nuclei were always digested. Experiments with dogs from whom the pancreas had been removed showed that the nuclei in these cases were undigested. Steele's observations verify in the main the contention of Schmidt as to the experiments on dogs, but he holds that the clinical importance of the test is not so great as was suggested by Schmidt. In a case of very extensive pancreatic cancer, the nuclei were digested, and in a case of achylia where there was no pancreatic disease the nuclei were undigested. He sums up by saying:—"The nucleus test is probably a rough indication of the presence or absence of pancreatic secretion, but the relation between the nuclei of muscle and pancreatic secretion may not be specific, and the persistence of nuclei may be the result of general lowering of all digestive power, quite as much as a sign of insufficiency of the pancreas alone." D.

The Physiological Limitations of Rectal Feeding.—Esdall (*Amer. Journ. Med. Sciences*, Nov., 1906) discusses the value of this procedure as a means of supplying food, not as a therapeutic method. The common belief that by this method a very considerable proportion of patients can be maintained on nutritive equilibrium is, he maintains, erroneous, and based on inaccurate observation. That the method has great therapeutic value is not denied. "It is decidedly better than simple starvation; but it is nearly always a marked degree of starvation, and should be recognised as such, and not given a higher place than it deserves." The value of the method depends on several factors. In the first place the local condition, for the treatment of which the method is adopted, is usually considerably benefited by it. The psychical factor is also of great importance, and Pawlow has shown the definite physical effects of such psychical factors. Another reason of the benefit of rectal alimentation is that the patients for whom it is ordered are usually suffering from lack of fluid. Nutritive enemas always contain a large proportion of fluid, and most of this is quickly absorbed, and tends greatly to the benefit of the patient. The salts, too, are in great part absorbed, and are undoubtedly of use in the organism. With regard to the proteids, fats, and carbohydrates, the matter is different; all are to some extent absorbed by the rectum, but much less freely than is commonly thought, and far less freely than when taken by the mouth. From experiments carried on by the writer and Dr. Miller, they found that the value of the food absorbed in their most favourable cases was less than 300 calories in the day, and usually not above 200 calories. "The latter amount is not one-sixth of the absolute demands of most persons, even of most sick persons, if they are to be kept from losing tissue, and especially if they are to have their nutrition improved." The fats, which have an especially high food value, are very badly absorbed; the proteids and peptones are somewhat more easily absorbed, but still only to a

small degree. In the case of the carbo-hydrates, estimation of absorption is of extreme difficulty owing to the bacterial decomposition of the sugars which takes place in the rectum. There is no doubt that in rare instances a larger degree of absorption than this has been observed, and these cases are explained by a reflux of part of the nutritive enema through the ileo-cæcal valve, and absorption in the small intestine. That reversed peristalsis does occur in the large intestine has been established by the observations of Cannon. "The difficulty does not lie in the absence of movements in the large intestine that would carry the food up to the ileo-cæcal valve, but in getting it to pass this valve." "In rare instances considerable amounts of food do actually get by the valve, and small amounts often or even constantly pass through, yet it is quite certain that, as a rule, no considerable proportion succeeds in doing so." Esdall approves Von Noorden's suggestion of using in nutritive enemas some of the end products of proteid digestion, such as amino-acids, rather than the native proteids, and also of the suggestion of Reach to substitute dextrins for other carbohydrates. These appear to be better absorbed, and are much less irritating, and less easily decomposed by bacteria than are the sugars. K.

Transitory Hemiplegia in Elderly Persons.—Edgeworth (*Scottish Med. and Surg. Journ.*, Nov., 1906) describes two cases of temporary hemiplegia which he attributes to "temporary arterial spasm involving a portion of the central vascular supply." In each patient there were attacks of clonic spasm, followed by transitory paralysis, which, on some occasions, were associated with mental derangement, while on other occasions there were attacks of mental derangement only. The plantar reflex was examined for in the second case only, and it did not become of the extensor type. Edgeworth considers that the absence of an extenso-plantar reflex affords a ready means of diagnosing the condition from one of hemiplegia due to some organic cause, where the reflex becomes of extensor type within a very short time. Edgeworth draws the following conclusions in regard to this class of case:—"(1) In elderly persons attacks of transitory hemiplegia may occur, which are probably not due to any persisting vascular lesion. The hemiplegia may or may not be preceded by loss of consciousness or clonic spasm in the subsequently paralysed parts. Or clonic spasm may occur which is not followed by paralysis. (2) If paralysis occurs it may be distinguished from that due to a permanent vascular lesion by the non-occurrence of an extenso-plantar reflex. (3) In such patients attacks of mental derangement, of similar transient character, may occur; they are probaly due to the same cause." K.

The Pancreatic Reaction.—Dr. P. S. Haldane (*Edin. Med. Jour.*, October, 1906), reports the conclusions that he has arrived at with reference to Cammidge's urinary pancreatic reaction, described in 1904. Since that date the writer of the paper has studied the tests, and formulates his results as follows:—(1) The test as a diagnostic aid for pancreatic disease has not proved of any real value, owing to the fact that a positive reaction is often obtained in normal urine. (2) The urine from the same individual (normal) may yield at different times negative, equivocal, or well-marked results. (3) The occurrence of crystals is largely affected by the degree of concentration of the fluid at the end of the process. (4) In the guinea-pig's urine crystals are obtained in every case, no concentration being required. (5) The inhibition of glycerine has very little effect on the reaction. (6) Differentiation in pancreatic disease by tests A and B (Cammidge) frequently leads to a wrong diagnosis. (7) The use of lead in the test is an additional source of fallacy, though not a very important one. M.

Tumours of the Frontal Region of the Brain.—The diagnosis of tumours of this region is discussed by Grainger Stewart (*Lancet*, Nov. 3rd, 1906). He points out in the first place that these tumours are generally characterised by an absence of signs pointing to involvement of other parts of the brain, rather than by definite focal signs. The general signs of intracranial tumour are, however, present. Optic neuritis is nearly always present, and in his experience it almost always appears first in the eye on the side of the growth, and is also most intense on this side. Mental symptoms may occur, but are not always due to the position of the tumour. When, however, the main changes are inattention, lack of concentration, and slowness in answering questions, they may be directly ascribed to disease of the frontal region. Fits and seizures which are never ushered in by sensory aurae are also commonly met with, and often resemble ordinary epileptiform attacks. As more direct diagnostic aids, he mentions unilateral anosmia, unassociated with nasal disease; tremor in the limbs of the side homolateral to the tumour, and most marked in the arm; diminution of the superficial abdominal reflex on the contralateral side; contralateral hemiparesis and contralateral extensor response on stimulating the sole of the foot; and, lastly, local external signs such as cranial tenderness and protrusion of the eye. M.

Formic Acid in Diphtheria.—Dr. Croom reports the results obtained by the treatment of 100 cases of diphtheria by formic acid (*Edin. Med. Journal*, Oct., 1906). He was led to give it as a general tonic, owing to the fact that the formates in general produce their musculo-tonic effect without having much action on the blood pressure, and thus contrast strongly with the more commonly-used drugs, strychnine, digitalis, and adrenalin. In every case the anti-toxin treatment was carried out as usual, but, in addition, from 5 to 20 minims of a 25 per cent. solution of formic acid was given four-hourly for ten to fourteen days, and then 5 to 10 minims three times daily for a further period of fourteen days. For purposes of comparison he has analysed 300 other cases, and finds: (1) that the percentage of death from cardiac failure in the cases treated by formic acid was 2 per cent.; in those not so treated 8.6 per cent. (2) that the percentage of paralyses was 3 per cent. in the treated cases, and 14 per cent. in the non-treated; (3) that albuminuria was much less common in the cases which took formic acid than in those which did not. The conclusion that the author derives is that a good case has been made out for the value of formic acid, and he strongly counsels its further use. M.

Gastrostaxis.—Under this title Dr. Hale White draws attention to cases of hæmatemesis caused by capillary oozing from the mucous membrane of the stomach, and usually confounded with cases of true ulceration (*Lancet*, Nov. 3rd, 1906). His attention was first called to it by the admission of a patient to Guy's Hospital suffering from severe and ultimately fatal hæmatemesis, and in whose stomach no trace of ulceration was found at the autopsy. On then studying the subject he was struck by the fact that post-mortem evidence shows gastric ulcer to be as common in men as in women, while the usually accepted symptoms of ulceration are much more often found in women. From this he concludes that many cases of so-called gastric ulcer in women are really examples of gastrostaxis, and in support of his thesis he adduces the clinical records of 29 cases in which the stomach was either examined during life by operation, or *post mortem*. Of the 29 patients, 27 were women, and in all the principal symptoms were recurring severe hæmatemesis and dyspepsia. In considering the etiology he excludes the theory of vicarious menstruation, and also states that some of his patients showed no signs of chlorosis. As a result also of pathological evidence, he concludes that gastric ecchymoses and hæmorrhagic erosions are not definitely connected with the disease. The prognosis is good when an operation is not performed, and the treatment simple, this last consisting of the usual treatment for gastric ulcer, with, however, an early return to gastric feeding. M.

NOTICES TO CORRESPONDENTS &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

DR. H. S. T.—It is important to exclude the possibility of chronic osteomyelitis of the lower end of the femur. This condition is liable to give rise to mistakes in the diagnosis of sarcoma, and should be seriously considered. An exploratory incision is quite proper treatment if X-rays and clinical examination fail to establish the diagnosis.

C_2H_6O.—The question of intoxication and its mechanism is as complicated as it is interesting. The toxic properties of the higher alcohols are proportional to their solubility and volatility. Natural wine containing comparatively few higher alcohols will seldom lead to chronic alcoholism. Absinthe and beer and so on produce a mixed intoxication, that in the case of absinthe being complicated by the convulsive action of oil of wormwood on the cerebrum. Ether intoxication is of a separate character.

M. H.—The name of the disease is probably sclerema neonatorum, if the hardness of the skin is as you describe.

DOVER.—Certainly. It would appear from Clause XVI. of the Central Midwives Board rules that midwives may administer poisonous drugs, for the rule runs that "The midwife must enter in a book . . . all occasions on which she is under the necessity of administering any drug, whether scheduled as a poison or not. . ." We do not know how one enters an "occasion" in a book.

DR. MONRO'S "Cases of Œsophageal Strictures" are marked for early insertion.

MR. F. B. M. (Hastings) is thanked for his letter, but the case is one of almost daily occurrence, and not worthy of special reference.

DR. ARANY (Budapesth).—It will afford us pleasure to receive it.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 5th.

OBSTETRICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. Handfield-Jones, Dr. H. R. Spencer, Mr. J. H. Targett, and Dr. W. A. Potts (introduced by Dr. Stevens). Paper:—Dr. V. Bonney: The Treatment of Ovarian Prolapse by shortening the Ovarian Ligament.

SOCIETY OF ARTS (John Street. Adelphi, W.C.).—8 p.m.: Colonel Sir C. M. Watson, K.C.M.G., C.B.: The Metric System.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Dr. C. Ryall: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Dr. E. F. Buzzard: Syphilis in the Nervous System.

THURSDAY, DECEMBER 6th.

NEUROLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Exhibition of Clinical Cases. Patients in attendance at 8 p.m.

NORTH-EAST LONDON CLINICAL SOCIETY (Tottenham Hospital, N.).—4 p.m.: Discussion on Notes from a Children's Clinic (opened by Dr. Reginald Brown).

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.)

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Hair: Hyphogenic Sycosis; II., Tinea.

HARVEIAN SOCIETY (Stafford Rooms, Titchborne Street, Edgware Road).—8.30 p.m.: Discussion on the "Modern Methods of Dealing with Ordinary Cases of Labour." To be opened by Dr. Robert Boxall, Dr. Horrocks, Dr. Handfield Jones, and others will take part.

FRIDAY, DECEMBER 7th.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Miller Hospital, Greenwich Road, S.E.).—8.45 p.m.: Purvis Oration:—Dr. A. M. Robson: Operative Treatment of Acute General Peritonitis. Conversazione.

LARYNGOLOGICAL SOCIETY OF LONDON (20 Hanover Square, W.).—5 p.m. Exhibition of Cases and Specimens.

SOCIETY OF ANÆSTHETISTS (20 Hanover Square, W.).—8.30 p.m.: Papers by Dr. Ll. Powell, Dr. G. H. A. Barton, M. A. de Prenderville, and Mr. L. K. Thomas.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Dr. L. Lack: Clinique. (Throat.)

TUESDAY, DECEMBER 11th.

MEDICO-LEGAL SOCIETY (22 Albemarle Street, W.)—8.30 p.m.: I., Exhibition of Medico-Legal Specimens. II., Discussion, "Some Limitations of Medical Evidence." To be opened by Stanley B. Atkinson, M.B., J.P.

Vacancies.

Monkstown Hospital, Co. Dublin.—Qualified Resident Medical Officer. Salary £40 per annum, with board, &c. Immediate application to Hon. Secretary. (See advt.)

Manorhamilton Union.—Temporary Medical Officer. Four guineas per week. Immediate application to Peter Kearnig, Clerk of Union. (See advt.)

The Grafton Club, Dublin.—Medical Officer. Applications to Hon. Sec. on or before Dec. 12th. (See advt.)

Royal Hospital for Incurables, Donnybrook, Dublin.—Resident Medical Officer. Salary £120 per annum, with board, &c. Immediate application to J. J. Thompson, Registrar. (See advt.)

Fisherton Asylum, Salisbury.—Second Assistant Medical Officer. Salary £120 per annum, with board, apartments, and washing. Applications to the Medical Superintendent.

The Middlesex Hospital, W. Medical Officer and Registrar to the Cancer Department. Salary £100 per annum, with board and residence. Applications to F. Clark Melhado, Secretary Superintendent.

Bristol General Hospital.—Senior House Surgeon. Salary £150 per annum, with board, residence, &c., in the house. Applications to the Secretary.

Glamorgan County Asylum, Bridgend.—Junior Assistant Medical Officer. Salary £150 per annum, with board, apartments, attendance, and washing. Applications to the Medical Superintendent.

Manchester Royal Infirmary.—Resident Medical Officer. Salary £150 per annum, with board and residence. Applications to the Chairman of the House Committee.

Blackburn County Borough.—Education Committee.—Assistant to the Medical Officer of Health. Salary £150 per annum. Applications to Alexander Gow, Director, Education Offices, Library Street, Blackburn.

Appointments.

BAYLEY, HARRY, L.S.A., Assistant Medical Officer to the Warkeford Hospital for Mental Diseases, Oxford.

DODD, STANLEY, M.B., B.C.Cantab., Obstetric Tutor at Westminster Hospital.

FEDDEN, W. FEDDE, M.S., M.B., F.R.C.S.Eng., Assistant Surgeon at St. George's Hospital.

GEAKE, G. B., L.D.S.Eng., House Surgeon to the Royal Dental Hospital of London and London School of Dental Surgery.

GRANT, J. DUNDAS, M.D., F.R.C.S.Eng., Surgeon to the Throat and Ear Department of the Hospital for Consumption, Brompton.

JACKSON, H. E., L.D.S.Eng., House Surgeon to the Royal Dental Hospital of London and London School of Dental Surgery.

KIDD, PERCY, M.D., F.R.C.P.Lond., Consulting Physician to the Hospital for Consumption, Brompton.

PITTS, A. T., L.D.S.Eng., House Surgeon to the Royal Dental Hospital of London and London School of Dental Surgery.

ROBERTSON, W. G., M.B., Ch.B.Edin., House Surgeon at the Hartlepools Hospital.

SIMPSON, W. B., M.B., M.S., D.P.H.Aberd., Medical Officer of Health of Grimsby.

SOUTHERN, W. D., L.D.S.Eng., House Surgeon to the Royal Dental Hospital of London and London School of Dental Surgery.

STEVEN, J. LINDSAY, M.D.Glasg., F.F.P.S.Glasg., Visiting Physician to the Western Infirmary, Glasgow.

WALL, R. CECIL B., M.D., B.Ch.Oxon., Assistant Physician to the Hospital for Consumption, Brompton.

WHALLEY, FREDERICK, M.D., Ch.B.Leeds, House Surgeon at the Leeds Hospital for Women and Children.

Births.

AUBREY.—On Nov. 28th, at Bitton, Bristol, the wife of Thomas Aubrey, M.B.Lond., of a son.

HADFIELD.—On Dec. 1st, at Mornington, Malvern Link, the wife of C. F. Hadfield, M.A., M.D. (Cantab), of a daughter.

HALAHAN.—On Nov. 28th, at 11, Stoke Terrace, Devonport, the wife of Staff-Surgeon T. J. Halahan, R.M., H.M.S. Diadem, of a daughter.

MARSHALL.—On Dec. 1st, at St. John's House, Lechlade, Gloucestershire, the wife of Thomas Bingham Marshall, M.R.C.P., L.R.C.P., of a son.

ROSS.—On Nov. 27th, at "Grange House," Burslem, Staffordshire, the wife of Wm. Levingston Ross. L.R.C.S. and L.R.C.P.I. of a daughter.

SELBY.—On Nov. 27th, at The Rock, Frodsham, Cheshire, the wife of T. J. Selby, M.B., of a son.

STONE.—On Nov. 27th, at 30, Nivern Square, South Kensington, the wife of Surgeon-Major C. A. Stone, R.A.M.C., of a son (stillborn.)

Marriages.

LATHAM—BAKER.—On Nov. 27th, at St. Martin's Church, Lincoln, Charles Hugh Latham, M.B., B.S.Lond., youngest son of the late Rev. E. Latham, M.A., Vicar of Matlock Bath, to Margaret Emily De Foe, only daughter of the late Canon W. De Foe Baker, Rector of Snelland.

PESEL—SWAIN.—On Nov. 29th, at St. Mary-at-the-Elms, Ipswich, Howard G. Pesel, M.D., of Thornton-le-Dale, Yorks. son of the late George Pesel, Huddersfield, to Florence Mary, eldest daughter of the late William J. Swan, Canterbury.

Death.

ROBERTS.—On Nov. 29th, at Broadstairs, John Coryton Roberts, L.R.C.P., M.R.C.S., L.M., of Avenue House, Peckham Rye, aged 65 years.

THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, DECEMBER 12, 1906. No. 24

NOTES AND COMMENTS.

The New Direct Representatives.

WE are officially informed that Dr. Langley Browne, Dr. McManus, and Dr. Latimer, have been elected as Direct Representatives on the General Medical Council for England, and Dr. Norman Walker for Scotland. The exact figures were not obtainable at the time of going to press.

The Proposed State Medical Service for Ireland.

A CONSIDERABLE amount of misapprehension appears to have arisen in the minds of some members of the Poor-Law Service in Ireland as to whether or not the proposals for reform of the Association are intended to apply to Dispensary medical officers. Some of this misunderstanding, we fear, has been wilfully encouraged with the object of casting discredit on the scheme, whilst more of it is genuine. The position of the matter is perfectly plain, and is this. The terms of reference of the Commissioners were limited, and did not include any reference to Dispensary Medical Officers. At the same time, the Commissioners saw that it was impossible for them to recommend any satisfactory scheme which did not include reform in the Dispensary system, and consequently they brought that system into their report by implication, and in such a manner as to make their intentions perfectly plain. It was never present in their minds that the reformed Workhouse and Infirmary medical system should alone be constituted a State service, and we can say in the most definite manner possible, and without fear of contradiction that their report advises and that they themselves intended inclusion of the Dispensary Service.

Edinburgh Cavalry.

THE way of the sanitarian is hard at the best of times, and people have yet to give the first consideration to questions of health. We cannot help sympathising with Mr. Haldane in the unpopularity he has incurred in Edinburgh through his concern for the health of the Scots Greys. For years medical men have been urging on the military authorities the paramount importance of disease-prevention if a little British Army is to go the proverbially long way, and with new men at the War Office a sprinkling of new ideas has come in and the soldier is beginning to find his "fitness" regarded as an essential element in his training. We who hope that this care may be still further extended cannot help regretting that the removal of the Scots Greys from the insanitary Piershill Barracks should be used as a stick to belabour the Minister for War. It is true that some experts are said to have pronounced the barracks in good sanitary condition; but Mr. Haldane has to be guided by Sir Alfred Keogh's advice, and his decision is strongly against the barracks. However, another consultation as to the condition of the barracks is to take place, and we can only hope that if the adverse opinion is sustained the patriotism of the good folk in Edinburgh will show itself by preferring healthy soldiers in England to unhealthy ones in Scotland, even though they be mounted on horses.

Clacton Doctor's Case.

WITH regard to the Clacton medical man to whose case we recently called attention, we have received from a well-known member of the profession, himself a magistrate for the town, a communication and a newspaper cutting which we have read with great interest. It will be remembered that the medical man of whom we wrote was charged and convicted of extraordinary conduct, and we expressed the opinion that an inquiry into his mental state should be made. We now learn that such an enquiry was made by two medical practitioners last September, and that he was pronounced sane. However, only last week the same gentleman was again before the bench, charged with being drunk and disorderly in the highway, and was unanimously found guilty of the offence. The Chairman, however, announced a decision of the magistrates with regard to his treatment which causes us great satisfaction. The defendant was remanded on bail for a fortnight, in order that the Home Secretary might be communicated with for instructions as to how to deal with him. We can only compliment the bench on their high sense of duty and responsibility, and this we do heartily.

Objection to Doctors.

MEDICAL men have to court unpopularity at times when their duty demands it, but it is rather a shock to learn that a man will for years suffer excruciating pain and even try to commit suicide rather than see a doctor. Such, however, was the case with a man aged seventy-two who was charged at the Clerkenwell Sessions last week with trying to commit suicide, and who pleaded guilty to the charge. The malady, the nature of which was not revealed, was a most distressing one, and for seven years he suffered till he could bear it no longer, and one morning he was found in bed with his throat partially cut. Fortunately for him a medical man was sent for, and succeeded in saving his life and alleviating his pain, so that the prisoner was subsequently in Court able to express sorrow for his folly. There are a certain number of people who —in health—boast that they would rather die than

see a doctor, but when the alternative presents itself, in our experience, they invariably choose the latter.

Associated Midwives, Unlimited.

COMBINATION is the order of the day, and far be it from us to decry the advantages to be derived therefrom, but we confess to feeling a little surprise on learning that the midwives of Manchester are enrolling themselves into a fighting force. We do not know what the grievances of midwives are: whether they object to calling in a medical man in difficult cases, or whether they regard the Manchester Supervising Authority as tyrannical in its administration. For ourselves we should have thought the midwives have had everything so much their own way that their lines would have been regarded as having fallen in pleasant places, but presumably we are in error. It seems that the Women's Trades' Council have taken the matter up, and have lent their rooms for the purpose, so that we presume midwives are going to regard themselves as "tradeswomen," and not as "professional ladies." And for that relief let us be truly thankful.

LEADING ARTICLES.

THE JOINT HOSPITAL CONFERENCE AND HOSPITAL REFORM.

THE awakening of the general practitioner, slow and partial though it be, is already bearing fruit. On December 6th a Conference representative of medical charities from all parts of the United Kingdom met together in London at University College. This important meeting had been organised by the Hospitals Committee of the British Medical Association, as the outcome of a serious attempt to grapple with the injury wrought upon the rank and file of the medical profession by the indiscriminate distribution of hospital relief. The movement, therefore, must be welcomed by every one who is interested in the future prosperity of a learned and humane profession, whose members now find themselves plunged into a morass of adversity due to causes of which that of unfair hospital competition is not one of the least important. From many points of view last week's Conference proved nothing more than the complexity of the whole question of hospital reform. As usually happens in medical politics, the engineering of the whole matter had fallen into a few hands, representing interests that could not be regarded as identical with those of the general practitioner. The chair, for instance, was occupied by Sir William Church, ex-President of the London Royal College of Physicians, a body that is absolutely autocratic and aloof from the faintest suspicion of modern democratic thought and progress. Then the chief resolution was moved by Sir Henry Burdett, an amiable gentleman whose name has long been honourably connected with charitable administration throughout the kingdom. It is not easy to see, however, why the weight of his non-medical authority should be suddenly thrown into the balance, and why he should claim to represent and protect the rights of medical practitioners. The Conference whom he addressed appeared to hold that view precisely. It fell to Sir Henry Burdett to move a general approval of the principles formulated by the Joint Committee. This he proceeded to do by an admirable and well-informed statement of the disproportionate growth of charitable medical relief during the past generation, but he said little about the principles that the meeting was asked to adopt. The significance of that statement may be gathered from the fact that there were no less than nineteen suggested model principles of hospital management, covering most of the burning questions involved in the relations of the medical charities, the public, and the profession. It seems an extraordinary proceeding, therefore, to summon a Conference, which it is proposed to hold annually, and to ask them at the outset to pledge themselves to an explicit policy drawn up in detail by a committee that must be regarded for that particular purpose as private and unofficial. Under these circumstances, it is little to be wondered at that the Conference refused to sign a blank cheque of this kind, and Sir Henry Burdett's resolution was hailed with a chorus of criticism and dissent. One speaker, for example, asked if the Conference was to pledge itself for all time to Principle XIII., which laid down "that though there is no objection to pay wards being connected with voluntary hospitals, provided that they are open to every member of the medical profession, who shall be paid any fee to be arranged by him and his patient." Even with the appended qualification, the objections to the pay system in hospitals are deeply rooted, and many medical men regard its adoption by Guy's, by St. Thomas's, and by various other general hospitals as an indelible blot upon their administration, and an unceasing injury to the general practitioner. Yet Sir Henry Burdett appeared to take it for granted that Section XIII. would secure the instant and hearty approval of every member of the Conference. The result of the discussion was the withdrawal of the original resolution pledging the Conference to accept a parcel of cut and dried principles, and the substitution of a declaration that they would "welcome the further discussion of the principles" laid before them. This result looks like a spirited attempt on the part of the hospital delegates to think and act for themselves. It is significant that Sir William Church, Sir Henry Burdett, and one or two of their supporters more than hinted their desire for an extended system of provident dispensaries. This proposal should be regarded with the closest scrutiny by the medical profession. Unless properly safeguarded, it would mean merely the substitution of one form of abuse for another. Assuming that general practitioners are appointed as medical officers to such dispensaries, it would simply mean the payment of a privileged few at the expense of the many, who would at the same time be deprived of a certain number of patients. The way in which professional philanthropists insist on the necessity of extracting money from

poor hospital patients is a thing to marvel at. They appear to overlook the obvious fact that the proper course is to curtail and control the present distribution of charity. To reduce the enormous volume of gratuitious medical relief by restricting it to the deserving poor is the last thing they propose. Their constant effort seems to be to extract larger and larger sums from the hitherto apparently almost inexhaustible stream of public benevolence. But the time has come when the heart must be governed by the head, and the bitter cry of the general practitioner has gone forth in unmistakable tones to the outside world. Under these circumstances we welcome the first Joint Hospitals Conference of Great Britain as a presage of a brighter future in the administration of our hospital system, which, after all, stands an enduring monument to the sweet humanity that lies deep in the heart of mankind.

CARDIFF SURGEONS' CASE.

The action for £2,000 damages for negligence in surgical treatment brought by Mr. Southern of Cardiff, against Mr. Lynn Thomas and Mr. Skyrme, ended last week in a verdict for the plaintiff with £100 damages. The case was tried at the Glamorgan Assizes a year ago with an indeterminate result, for the jury then were unable to agree; this time the *venue* was changed to the High Court, where Mr. Justice Bigham with a jury heard the case. The plaintiff in the action was a mining engineer, who in July, 1904, as the result of a bicycle accident, sustained certain injuries, the chief of which was one to the right shoulder. He called in Mr. Skyrme, a general practitioner at Cardiff, who diagnosed a sub-glenoid dislocation of the humerus, which he reduced by putting his foot in the axilla and pulling on the forearm. Mr. Skyrme, in the course of his examinations and manipulations, found further trouble and called in Mr. Lynn Thomas. Together they diagnosed a fracture of the surgical neck of the humerus, but in consequence of the extensive bruising of the soft parts which had occurred, they decided that, in view of the danger of gangrene, no further treatment than placing a pad in the axilla and bandaging the upper arm to the side would be justifiable. As a matter of fact, great swelling of the arm subsequently occurred, and when a Röntgen ray photograph was afterwards taken, it was found the fragments of the bone overlapped and were becoming joined by side-to-side and not end-to-end union. The lower fragment was drawn upwards and inwards into the axilla, while the upper fragment was pulled outwards. To cut a long story short, the patient recovered with a good deal of stiffness of the shoulder, which, considering the extensive damage to the soft parts and the subsequent adhesion, was not surprising. The case tried in London was long drawn out, and considering that Mr. Rose, Mr. Pepper, and Mr. Battle gave evidence for the plaintiff, and Mr. Bowlby, Sir Frederick Treves, Mr. Mansell Moullin, Sir William Bennett, Mr Arbuthnot Lane, Mr. Page, Mr. Edmund Owen, and Mr. Waterhouse for the defendant, it cannot be said that the jury lacked the opportunity of deriving information as to the propriety of the treatment. However, after an hour's consultation they reported that they could not come to a unanimous decision, and on being sent back by the judge, they reported after another half-hour that they were still not entirely agreed; again the judge sent them back, and after further hesitation they sent a note into Court, raising a question which practically amounted to asking direction from the judge as to their verdict. Finally, after being repeatedly urged by the judge to come to a decision, they found for the plaintiff with £100 damages. Naturally the defence applied for a stay of execution with a view to appeal, and after some argument this was granted on certain conditions. The case standing thus at the time of writing, we are precluded from commenting on it as we should like to do. It is a matter of vital concern to medical men in every branch of practice that treatment deliberately adopted by a well-equipped general practitioner in consultation with an eminent hospital surgeon should be regarded as "negligent" by a jury, and this result, if allowed to stand, raises serious questions as to the relation of the profession to the public. Of this we shall have more to say later. At present it is pertinent to point out that the costs of this action are bound to be of ruinous dimensions. Taking the figures suggested by a leading Welsh newspaper, it seems the necessary expenses will be some £5,000 or £6,000, and when the untaxed costs between solicitor and client are taken into account, they will reach some £8,000. We are not prepared to support these figures as given, but that the total will be prodigious is certain, and it must be remembered that this is the second trial.

NOTES ON CURRENT TOPICS.

Lunacy and Public Health.

The rather curious step lately taken by the Government with regard to the Royal Commission on the Care and Control of the Feeble-minded, namely, extending the reference in the middle of their sittings so as to bring general lunacy administration under their investigation has of course immensely increased the scope of their enquiries. It may not have been an altogether convenient method of procedure, but the need for enlarging the Lunacy Commission, or otherwise dealing with the central administration of the lunacy laws was urgent. At the sitting last week Sir James Crichton-Browne gave evidence of an interesting character, and those of the Royal Commissioners who are possessed of an imagination should find his suggestions, in one respect at least, worthy of deep reflection. While opposed to any co-ordination of the functions of the Lord Chancellor's Visitors and the present Commissioners in

Lunacy, Sir James proposed as an ideal that there should be a Board of Health, with its own Cabinet Minister, which should embrace in its purview the care and treatment of the insane, and, moreover, pursue investigations into the factors that conduce to insanity. It will probably come to the lay public as a surprise—indeed it has already done so if we judge from the expressions we have seen—that mental disease is disease that should be treated in conjunction with and on similar lines to bodily ailments, and that it is amenable to preventive treatment. Lunacy is still regarded as a legal status and not as a cerebral affection, and the surest way to secure proper conceptions with regard to it in the public mind would be to remove lunacy treatment altogether from the Lord Chancellor's department, and to bring it into line with public health administration.

Medical Men and Money-Lenders.

The persistency with which money-lenders circularise the medical profession is a sad comment on the welfare of some of our weaker brethren. Like any other form of advertisement, it would not be sustained over a long period of time unless it proved remunerative. Medical practice, especially in the present days of remorseless competition, is apt to drive unfortunate practitioners through penury into the nets of usury. Last week's bankruptcy records revealed the case of an Essex medical man who had become involved in the coils of that most venomous hydra, the Hebrew money-lending solicitor. It is somewhat a matter of wonder that the Incorporated Law Society permit members of the legal profession to embark in such transactions. However, in this particular instance the borrower appears to have been alive to the sharp practices to which he was subjected in his anxiety to raise various loans. The question of usury as it affects the public has never been firmly handled by the legislature. When that desirable attitude is attained by Parliament we may hope that the issuing of undesirable circulars, such as those of patent medicine vendors, racing tipsters and money-lenders may be prohibited under heavy penalties.

Gratuitous Medical Certificates.

Were the medical profession to protest with united action against the granting of certificates without fee they would speedily gain their point. In the case of school boards an immense number of certificates are obtained from medical men without payment. This mistaken policy is often the result of sheer kindness on the part of medical attendants, who are unwilling to put poor people to unnecessary trouble or expense. Obviously the School Board, maintained at the expense of the ratepayers, should pay a reasonable fee for the certificates that enable them to exercise an adequate control over the attendances of scholars. At Acocks Green Police-court, Birmingham, last week in a non-attendance case an inspector asked why Dr. Ganner, a medical man, wanted the Education Committee to pay for a certificate. The gentleman referred to based his refusal upon the fact that the certificate was wanted by the Education Committee and not by the parents. Therefore the former should pay a fee for his services. The boy had not attended school on his advice, as he was ill. He advised the school inspector to try and get an expression of opinion from a solicitor for nothing. The case was dismissed, and the refusal of Dr. Ganner was thereby justified. If all medical men would agree to refuse school certificates without pay the point would have to be conceded. This matter would be worth the attention of the General Medical Council, had they any time to spare for so plain and prosaic a duty as the protection of the rights of the medical practitioner.

The Anæsthetist's Responsibilities.

IN France some months since, the relatives of a man who had died under chloroform brought an action against the medical man who administered the anæsthetic, claiming £2,000 damages. The claim was based on the fact that he had not warned the deceased, an alcoholic, of the possibility of a fatal result. It was not even suggested that the administration was in any respect faulty, but it was urged that it was imprudent to give chloroform to a man who was notoriously alcoholic and had fainted twice shortly before the operation. The Court of First Instance at Chateau-Thierry awarded £320 by way of damages on the grounds (1) that the patient being an alcoholic rendered the administration of chloroform peculiarly dangerous; (2) that his condition was not such as to place his life in danger; and (3) that under these circumstances he ought to have been warned of the possibility of a fatal issue. This decision naturally created much perturbation among practitioners, and an appeal was at once entered. Judgment has just been rendered by the higher Court of Amiens quashing the previous decision. The "motives" prompting the revision are worth recording: The Court declined to admit that alcoholism constituted a contra-indication for administering chloroform, seeing that it was a common practice in the Paris hospitals in urgent cases to give it to workmen even actually under the influence of alcohol. The fainting, declared the judges, was no doubt due to the pain caused by the movement of the damaged arm, and in no wise proved any inherent tendency to syncope. With regard to the allegation that an anæsthetic ought not to be given unless the patient's state is such as to threaten life, the Court state that the view "is not one which can be seriously advanced" in view of the absurd restrictions which such a decision would place on the use of anæsthetics in general, seeing, moreover, that chloroform lessens rather than increases the risk of syncope by abolishing pain, which would entail greater danger than the infinitesimal risk attached to the inhalation of

chloroform. Lastly, with regard to the fact of the doctor not having warned his patient of the risk, the Court point out that the danger of chloroform appears to lie more particularly in the impressionability of the patient, consequently that any such warning would infallibly have materially enhanced the risk. On the contrary, the doctor's duty is to reassure his patient, and not to alarm him unnecessarily. The Court added that the patient was evidently cognisant of the fact that he was running some risk seeing that he said to a friend who was present, "You will go to my funeral after all." It is a pleasure to record a judgment so intelligently "motivated" and one shudders to think of the disastrous consequences that would have accrued to suffering patients had the foolish decision of the first Court been upheld.

Clay Poultices made in Germany.

A weird story of unqualified medical practice comes from Bath. It appears that the four-year-old daughter of a banker was lying ill in that ancient city The father telegraphed from Egypt to a non-medical assistant at a consumptive home in Germany, named Eickche, to go and attend the child at Bath. When he arrived the local medical man naturally retired from the case. Two trained nurses were left, and one of them stated that under Eickche's directions she applied to the patient's chest poultices made of clay taken from the garden, put on cold, between muslin. These poultices were kept on two hours, until they became quite hot. The child also had cold baths, gradually increased to six in a day. When the day was bright the child was placed in a sunny spot in the room, undressed and lying in its cot. This line of treatment was not unnaturally brought to a speedy end by the death of the patient, and Eickche has fled the country. If unqualified medical practitioners are wanted, surely there are enough of them here at home without sending for them to Germany. The laws of the United Kingdom demand a long and costly training, and stringent examination tests before any person is permitted to practise as a medical man. Yet any quack may fleece the public right and left and acquire huge sums of money by fraudulent cures of the clay poultice order.

PERSONAL.

H.R.H. the Duke of Connaught, K.G., has graciously accepted the position of one of the Vice-Patrons of the North London or University College Hospital.

Sir Edwin Galsworthy, who has been connected with the Metropolitan Asylums Board since its establishment forty years ago, and for several years past as its chairman, has now resigned, to the great regret of his colleagues.

Dr. Thomas John Carson has been appointed Coroner for the borough of Oldham. He was Mayor of the borough last year, and resigned his office of Alderman in order to be eligible for the post of Coroner.

An unfavourable report is given of Dr. Hébert, whose condition is causing grave anxiety to his medical attendants at the Paris Hospital.

Sir Joseph Fayrer, Bart., Physician Extraordinary to the King, celebrated his 82nd birthday on December 6th.

Dr. Nuttall has resigned the Readership of Hygiene in the University of Cambridge, and it is recommended that a Lectureship of Hygiene be instituted.

Dr. MacAlister, Dr. Humphry, and Dr. Barclay Smith have been appointed members of the Cambridge University State Medicine Syndicate for three years.

Lieutenant-General W. H. Douglas, C.B., will inspect the Volunteer Ambulance School of Instruction for London and the Eastern District and present the prizes on December 12th.

The 1907 annual meeting of the British Medical Association will be held at Exeter, under the Presidency of Dr. Pavy, Senior Physician to the Royal Devon and Exeter Hospital. The last visit of the Association to that ancient city was in 1871.

The address on "Surgery" at the Exeter meeting will be delivered by Mr. Butlin, and that on "Medicine" by Dr. Hale White.

A stay of execution has been granted in the case of Southern v. Skryme and Lynn Thomas, so that more may yet be heard of this long and costly litigation.

The Hughlings Jackson lecture before the Neurological Society was delivered by Sir Victor Horsley on "Recent Research on Dr. Hughlings Jackson's Views on the Function of the Cerebellum."

The result of the election of a direct representative for Scotland on the General Medical Council was declared on Saturday. Dr. Norman Walker, Edinburgh, was elected by a majority of 429 votes over his opponent, Dr. William Bruce, of Dingwall.

Sir Richard Douglas Powell (President of the Royal College of Physicians), Mr. Henry Morris (President of the Royal College of Surgeons), and Dr. Kingston Fowler (Dean of the Faculty of Medicine of the University of London) were entertained at a congratulatory dinner on the 4th inst., at the Café Royal, by their colleagues of the Middlesex Hospital. Mr. Andrew Clarke was in the chair.

Dr. D. J. Coffey, Professor of Physiology in the Catholic University School of Medicine, Ireland, has been appointed Dean of Faculty of the School for the coming year, in room of Sir Christopher Nixon, who vacated the post on his appointment as Vice-Chancellor of the Royal University of Ireland.

The Manchester Port Sanitary Authority have agreed to ask the Board of Trade to appoint Dr. Dearden as medical officer under the new Merchant Shipping Act.

Dr. C. A. Ball has been appointed surgeon to Sir Patrick Dun's Hospital, Dublin, in place of Professor E. H. Bennett, who has resigned.

The leave of absence of Dr. G. A. Finlayson, Pathologist of the Medical Department, Singapore, has been further extended for two months from the 11th instant.

A CLINICAL LECTURE ON CHOLELITHIASIS.

By WILLIAM TAYLOR, M.B., F.R.C.S.I.

Surgeon to the Meath Hospital and County Dublin Infirmary; Member of the Council, Royal College of Surgeons, Ireland.

GENTLEMEN,—The patient before us was sent to me by Dr. David Jackson. The history of her illness is shortly as follows:—For some thirteen or fourteen years past—she is now 41 years old, married, and the mother of nine healthy children—she had been complaining of that condition which is commonly, yet somewhat vaguely, described as indigestion. She was seldom free from discomfort, but at times she experienced intense pain which started in the upper part of her abdomen—as she described it, in the pit of her stomach: that is, the epigastrium—and radiated thence round the right side and into the back of the right shoulder. When asked to show where she felt the pain in the back, she placed her hand over the lower portion of the right scapula.

Several times in the early period of her illness she has been confined to bed for three or four days at a time, and on a few occasions for a week or two. During the past four years she would be a week or ten days in bed and then up for a similar period, so that she was becoming a confirmed invalid. Quite recently she came to live on this side of the Liffey, and sent for Dr. Jackson to see her for the first time a few days before her admission here.

Dr. Jackson very correctly diagnosticated the cause of her trouble at his first visit, and suggested she should place herself under my care. Her condition on admission was that of a moderately well-conditioned woman. The skin was quite clear and the eyes bright. Though then free from severe pain, she experienced a slight dragging sensation and felt a sense of discomfort in her epigastric region. On palpation of the abdomen, the only abnormality to be detected was a slight amount of rigidity of the upper third of the rectus muscle on the right side, and some degree of tenderness on deep pressure immediately below the right costal arch. On sinking the fingers deeply underneath the right costal arch, and asking the patient to take a deep inspiration, at first she seemed to breathe freely and easily, but the moment the inspiration reached such a point that the fingers felt the liver touch them through the abdominal wall her respiration became suddenly arrested as if she was caught in a vice, and she complained of feeling a pain as if she had been stabbed.

Mayo Robson's tender point was next looked for and found to be present—that is, a tender point situated about 1 to 1½ inches above and to the right of the umbilicus. It is elicited by pressure of one finger along a line drawn from the junction of the ninth rib with its cartilage to the umbilicus, and is analagous to McBurney's tender point in appendicitis.

A painful area was also found on pressure in the back about two inches to the right of her spine and situated opposite the 11th and 12th dorsal and 1st lumbar vertebral spine. She was troubled with constipation. The urine is clear and free from albumen, and she has never been jaundiced. The clinical features were those of gall-stones in a gall-bladder, associated with a chronic cholecystitis and in all probability adhesions. The gall-bladder was not palpable. The diagnosis made before operation was gall-stones, on account of the repeated attacks of biliary colic, and chronic inflammation of the gall-bladder on account of the tenderness on pressure below the right costal arch and the sudden arrest of the respiration on taking a deep inspiration while the fingers were being pressed deeply below the ribs. That the gall-bladder would probably be found sclerotic and contracted was assumed from the long history and the knowledge that this is the common pathological change that takes place in old-standing cases of gall-stones that are causing trouble. Adhesions were diagnosticated for the same reason, and on account of the dragging pain. At the operation, which was performed two days after admission, on opening the abdomen in the usual way through the outer third of the right rectus muscle we first encountered the right border of the great omentum adherent all round the area below the right lobe of the liver. The gall-bladder was not to be seen anywhere. A large sponge was placed well down in the right kidney pouch, and elsewhere around; as adhesions were gradually separated, sponges were placed with the object of diminishing any risk of infection of the rest of the peritoneal cavity. On separating the omentum, the hepatic flexure of the colon and the duodenum (first stage) were found adherent to the under aspect of the liver, and what subsequently turned out to be the gall-bladder. With some difficulty the intestines were separated, and the gall-bladder freely exposed and found to contain calculi. After palpating the bile ducts, the gall-bladder was pulled forward and opened. Four fair-sized calculi were removed, but the finger inside could still detect calculi which seemed to be separated from the finger by a small amount of tissue. It was thought these might possibly be lying in a diverticulum of the gall-bladder, and as this viscus seemed but a useless appendage, it was decided to remove it. As it was being separated from the under surface of the liver, an abscess cavity was opened in the liver from which nine large-sized calculi were extracted. These had probably ulcerated from the gall-bladder into this position. The gall-bladder having been removed, and the abscess cavity cleaned out, the ducts were once more examined, and found free. A tube was then placed in contact with the cystic duct and fastened thereto by a single fine catgut suture. A small piece of gauze was packed loosely around it and into the cavity in the liver, and the rest of the abdominal wound closed by sutures. The patient, as you can see, has made an uninterrupted and rapid recovery.

With regard to the etiology of biliary calculi, I will merely state that bacterial invasion in a more or less attenuated form seems to play the most important part in leading to the production of gall-stones. The organisms gain entrance either through the common bile duct from the intestines, or through the portal vein. Much has recently been written in connection with this latter channel as the path of infection, and much experimental work in this direction has been done. Inflammatory or ulcerative lesions of the intestinal tract, in opening up a path for the entrance of organisms, is probably of great importance. This may explain the frequency with which gall-stone troubles are met with in patients subsequent to attacks of enteric fever. During recent years, too, attention has been drawn to the association of appendicitis and gall-stones. Lesions of the appendix would doubtless open up the path for infection of the blood in the portal system. Gall-stones are met with about four times more frequently in women than in men. The condition is much commoner after 45 years of age, but calculi which form at an advanced period of life do not produce

symptoms with such frequency as when they form before 50 years of age. Gall-stones are composed chiefly of cholesterin, with a variable amount of bile pigments and calcium salts. There may be only one calculus or there may be thousands, and their size varies inversely with their number. Multiple calculi are always facetted, and they almost always form in the gall-bladder. The pathological changes induced by gall-stones are many and diverse. I will enumerate only those most frequently seen, and pass over those of greater rarity.

Cholecystitis or inflammation of the gall-bladder is the most common. It varies in severity from what may be termed slight evidences of catarrh of the lining membrane to the most virulent types of acute phlegmonous inflammation ending in gangrene of the entire viscus. Such a condition generally gives rise to a rapidly spreading acute septic peritonitis. Repeated attacks of a milder type of inflammation spreading through all the coats of the gall-bladder ultimately lead to sclerosis and shrinkage, while adhesions are almost certain to be met with binding the pylorus, duodenum, colon, or great omentum to it more or less firmly, thus leading to a variety of complications, such as dilatation of the stomach and intestinal obstruction.

Sometimes calculi lead to ulceration of the gall-bladder and find their way into a mass of adhesions producing a localised abscess; or perhaps they ulcerate through the wall of an adherent piece of intestine, and thus escape, to produce intestinal obstruction, or perhaps to pass out without causing further trouble. (Nature's attempt to cure). In the case of the patient before us ulceration took place into the liver, producing abscess therein. A gall-stone may pass into the cystic duct and lodge there, thus producing distension of the gall-bladder with mucus — the so-called hydrops vesicæ fellæ—provided the gall-bladder is capable of distension.

Infection following upon such a condition produces empyema of the gall-bladder, or distension of the gall-bladder with pus. A stone which was impacted in the cystic duct, even after its passage or removal, may later lead to hydrops through the cicatrisation of an ulcer produced by its pressure. Gall-stones not infrequently pass on into the common duct and produce a temporary obstructive jaundice, or may become lodged therein more permanently, and thus produce chronic obstructive jaundice. Such a condition as the lodgment of a stone in the common duct is invariably attended by, or associated with, the development of an infective inflammation of the ducts right up into the liver substance—infective cholangitis—which may induce abscess in the liver, or more general suppurative hepatitis. A calculus may become impacted in any part of the common duct, including the ampulla. A stone lodged in this latter situation may be followed by the development of inflammation of the pancreas, which may be either acute or chronic. This by no means completes the list of pathological phenomena which may be met with, yet I would be failing in my obligations to you were I to omit to draw your attention to the association between cancer of the gall-bladder and biliary calculi. Cancer of the gall-bladder is seldom if ever met with unless associated with, and in all probability subsequent to, the development or formation of gall-stones in that viscus. In concluding my remarks on the pathological changes induced by cholelithiasis, let me say that calculi induce changes in the liver itself, such as cirrhosis and the development of an important, though by no means invariable change that is commonly associated with the presence of calculi in the gall-bladder, viz., the formation of Riedel's lobe—a tongue-shaped process which projects downwards from the right lobe. Riedel puts forth the opinion that the gall-bladder in its enlargement gradually drags downwards this tongue-shaped process. Moynahan, however, mentions having seen the condition well marked in the absence of gall-stones when operating for other abdominal conditions.

Now, with respect to symptoms and signs, I may say at the outset that gall-stones may exist for years in a gall-bladder and yet may not produce any symptoms or signs by which their presence can be detected. This simply means that inflammation of an acute or sub-acute type has not been induced in the gall-bladder. It is stated, however, that if a large number of patients be taken who complain of gastric trouble or discomfort vaguely described as "indigestion," in by far the larger majority gall-stones will be found in the gall-bladder. "Indigestion," therefore, is generally mentioned as the most common symptom of gall-stone disease. When gall-stones produce evidence of their presence, this evidence must be as varied as the pathological changes they may induce, but it is obvious they lead to recognition in one of two ways.

First by causing irritation, thus facilitating infection and inflammation, and secondly by passing along the ducts either cystic or common and in their passage exciting muscular spasm or becoming impacted in either of these ducts. The phenomena thus produced consist of some or all of the following features:—

(1) Pain, which may be localised, referred, or typical biliary colic. The localised pain is generally felt over the gall-bladder area, and may be either dull, aching, or sharp and severe and dependent upon distension or inflammation therein. The referred pain is most commonly described as being felt in the back of the right shoulder—the inferior angle of the right scapula; but it may be referred to the front of the chest. Sometimes it radiates from the epigastric region round the entire right side. The typical colicky pain is characterised by the suddenness of its onset, by its intensity, and by the abruptness with which it ceases. This colic is, therefore, in all probability due to the irritation and spasm excited by the passage of the stone along the ducts, and it lasts just so long as the stone is moving along. In all probability it is indicative of a violent effort on the part of the unstriped muscle in the wall of the duct to overcome the obstruction produced by the stone and drive it out.

(2) Nausea, retching and vomiting are, apart from the so-called "indigestion" the commonest features of gall-stone trouble, and are probably reflex in their origin. The severity and persistence of the vomiting have been known to lead to the death of the patient.

(3) Jaundice is not by any means so common a feature of gall-stone trouble as those mentioned. It is doubtful whether it will be met with in even 40 per cent of the cases. When present, it indicates either impaction of a stone in the common or hepatic duct, or infection and inflammation of these ducts. It has been occasionally found to be due to the pressure on the common duct of a large stone lodged in the cystic duct. In these cases the urine contains bile pigments, while the fæces for the time being become light-coloured.

(4) Fever is a common accompaniment. It is characterised by the rapidity of its rise and the suddenness of its fall. Moynahan has very aptly described the chart as the "steeple" chart of gall-stone trouble, and he considers this type of fever pathognomonic of gall-stone disease. Murphy, of Chicago, also speaks of these rapid variations of temperature as characteristic and calls the condition the "temperature angle of cholangeic infection."

(5) Tumour is due to distension of the gall-bladder. It may be due to an acute obstruction of the common duct in an early case, but is most frequently due to blocking of the cystic duct by a stone, or some other condition leading to its occlusion. In the large majority—75 to 80 per cent.—of old-standing cases of cholelithiasis the gall-bladder is either bound down by adhesions to such an extent that it cannot distend or its walls have become thickened and sclerotic from repeated attacks of inflammation and it exists only as an atrophic, useless and possibly dangerous appendage which is incapable of being distended so as to produce a palpable tumour.

Time will not permit me to go into the special features of gall-stone disease, for that would mean going into the manifestations of all the various pathological changes previously mentioned. I will merely mention that stones in the gall-bladder are recognised chiefly

by the evidences of cholecystitis—pain, localised and referred, tenderness on pressure over the gall-bladder, possibly muscular rigidity of the right rectus in its upper third, and Mayo Robson's tender point.

A stone in the cystic duct causes severe biliary colic, pain due to distension of the gall-bladder, which may be palpable and produce tumour, nausea, and vomiting without jaundice.

A stone in the common or hepatic duct causes severe colic, nausea, vomiting, jaundice with pigmented urine and light-coloured stools, and spiky temperature, with shivering fits and sweating.

A stone in the common duct may lead to chronic obstructive jaundice, which may last for months or years, and which must be carefully distinguished from another common cause of chronic obstructive jaundice, viz., cancer of the head of the pancreas.

In the chronic choledochus obstruction arising from stone, the history dates back for a long period—months or years—and is characteristic of cholelithiasis; there are repeated attacks of biliary colic with nausea and vomiting, and the jaundice develops suddenly after such an attack, is very remittent, and varies in its intensity from day to day, or week to week, being well-marked immediately after an attack of pain and vomiting and then gradually becoming less marked until it appears only as a sallowness of the skin, to reappear in intensity after another attack of pain. The urine and fæces likewise vary. When the jaundice is increasing in intensity after an attack of pain, the urine becomes deeply pigmented and the fæces assume a light appearance, but in a couple of days the jaundice begins to fade, the urine becomes less deeply coloured until it may become almost normal again, while the fæces become brown or dark again. Rigors with sharp pyrexial attacks, followed by sweating, are common, and it is but seldom one can palpate the gall-bladder—in fact it is generally contracted.

In cancer of the head of the pancreas the history is short—a few weeks at most—the onset of the jaundice is painless and gradual, or if not quite painless, the pain is certainly not that of biliary colic. The jaundice once it appears varies only by becoming more intense from day to day and week to week until the skin assumes a yellowish green or greenish black appearance—a greenish tint in a jaundiced skin is very suggestive of cancer—the urine continues to get darker in colour from day to day until it becomes quite black like porter, while the fæces are quite light in appearance—a drab colour. There are no rigors or pyrexial attacks as a rule, and in the large majority of cases the gall-bladder is readily palpable as a pear-shaped tumour, and in thin subjects it may easily be seen projecting under the abdominal wall and passing down as far as, or even below, the umbilicus. Here I would impress upon you the importance of Courvoisier's law—"That in chronic obstructive jaundice due to blockage of the common duct a distended gall-bladder indicates that the cause of the obstruction is due to something other than stone, most likely cancer of the head of the pancreas, or possibly cancer of the duct itself or duodenum at the point of entrance of the common duct. If the gall-bladder is not distended (contracted) the cause of the obstruction is stone." This rule will be found to hold good in fully 90 per cent of cases.

The reason of this is obvious from what I stated in connection with the pathological changes calculi induce.

The points in the physical examination of the patient I have drawn your attention to in reading the history of this case.

The diagnosis in typical cases is easy, but in other cases the best one can do is to make a presumptive diagnosis, or perhaps an alternative diagnosis. The conditions most likely to be confounded are ulcers of the pylorus or duodenum, appendix trouble where the cæcum remains undescended, movable kidney and occasionally renal calculus. The latter two conditions are not so likely to cause confusion and difficulties in diagnosis as the former two, and the best that can be done at times is to make an alternative diagnosis.

Prognosis.—Once gall-stones have declared their presence, it is doubtful whether anything short of operative treatment can have any lasting effect. Rest, dieting, and the "Carlsbad cure" will subdue the inflammation and give relief, but, as long as the gall-stones remain in the gall-bladder, or ducts, cannot be expected to cure. The surgical treatment of gall-stones in a gall-bladder but slightly altered in structure consists in removal of the calculi and drainage of the gall-bladder by suturing the edges of the opening into it to the parietal peritoneum and posterior sheath of the rectus muscle—not to the superficial structures or skin—cholecystostomy. In other cases where the gall bladder is structurally much altered it is better practice to remove it. A fairly useful guide for the beginner to follow with a view to determining whether he should remove the gall-bladder or simply drain it is as follows: "Generally speaking, gall-bladders which at operation are found to contain bile may be drained, as, if bile can get into them, the mucus they secrete can get out." "Bladders which are suspiciously thick and hard should be removed." In this way very early cancers may be extirpated with every prospect of cure.

Gall-stones firmly impacted in the cystic duct may be removed by incision of the duct over the stone (cysticotomy) followed by drainage of the gall-bladder, or, a still better treatment is removal of the gall-bladder and portion of duct with the stone impacted *in situ*. If it is considered necessary to drain the hepatic ducts this can easily be accomplished by passing a tube through the opening in the cut cystic duct and running it up into the hepatic duct where it can be fixed by passing a fine catgut suture through the wall of the cystic duct and tube. Gall-stones impacted in any portion of the common duct except the ampulla are treated by choledocotomy, or, cutting down on the stone, extracting the calculus and subsequently draining the ducts by passing a rubber tube through the opening in the duct and running it up to the hepatic duct, and then fixing it by passing a single fine catgut suture through the wall of the duct and the tube. A small piece of gauze packing should be placed around the tube. The opening in the common duct may be closed by suture if desired, and the gall-bladder opened and drained, but drainage through the opening in the common duct is the more preferable procedure. Of course, if the gall-bladder is structurally much altered, it should be removed, when drainage can be employed through the cystic duct and the common duct sutured. A stone impacted in the ampulla must be removed by opening the second stage of the duodenum transversely through the anterior wall opposite the ampulla. The mucous membrane over the stone is then incised from within the duodenum and the calculus extracted. There is no occasion to suture the cut mucous membrane. The duodenal opening is closed with two rows of suture in the ordinary way. The rest of the ducts are explored and the gall-bladder opened and drained or, if necessary, removed and the ducts drained through the open cystic duct. Occasionally a stone impacted in the retroduodenal portion of the duct can only be extracted by incising the duodenum as above, and then cutting directly down upon the stone through the posterior duodenal wall and duct, which is closely applied thereto. After extracting the calculus it is usual to pass one or two catgut sutures through the incised duct and duodenal walls, after which the primary incision in the duodenum is carefully closed as before. This procedure is sometimes called Kocher's choledochoduodenostomy.

Let me state that I do not think at present any sane modern surgeon would extract calculi out of a gall-bladder, then suture up the opening, drop the viscus into the abdomen, and close the abdominal wound without drainage. Such a procedure courts disaster, and shows absolute ignorance of the great principle of gall-stone surgery, which is to remove not only the calculi but to get rid of the infection and thus arrest the inflammation which led to their production. This principle means "drainage."

A word in conclusion on the mortality of these different operative procedures.

The mortality at present of cholecystostomy in an otherwise uncomplicated case is, I feel sure, all round well under 1 per cent.; in fact, in the last series of over 450 cases of simple gall-stone disease in the clinic of the brothers Mayo, the mortality was less than half of one per cent.

In the operation of cholecystectomy for gall-stone disease as distinct from cancer the mortality is probably about 2·5 to 3 per cent.

The mortality attending the operation of choledocotomy rises considerably higher, and seems to vary in the hands of different surgeons whose experience is sufficiently large from which to draw conclusions from 2 per cent. in the quiescent period to 11.7 per cent. in acute cases. The mortality at the least is about five times as great as if the calculi were confined to the gall-bladder. The reason of this is that two serious elements are introduced in common duct surgery, viz., jaundice and infection, and the mortality both immediate and remote depends entirely, or almost so, upon these two factors. In very chronic cases, too, the function of the liver cells becomes so completely disorganised that even after the obstruction is removed and drainage instituted they never regain their power to functionate and secrete bile again, death taking place in a day or two, the ducts at operation in such cases contain nothing but mucus. The important deduction to draw from this statement of the mortality of these different procedures is to recognise the trouble while the calculi are still in the gall-bladder and have them removed with the minimum of risk.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Francis Warner, M.D. F.R.C.P.Lond., F.R.C.S., Senior Physician to the London Hospital, "On Defects in Development: Their Significance," delivered at the London Hospital on October 31st, 1906.*

ORIGINAL PAPERS.

TWO CASES OF ŒSOPHAGEAL STRICTURE,

ONE MALIGNANT AND ONE CICATRICIAL,

TREATED BY GASTROSTOMY. (a)

By T. K. MONRO, M.D., F.F.P.S.G.,
Physician, Glasgow Royal Infirmary;
AND
A. N. M'GREGOR, M.D., F.F.P.S.G.,
Assistant-Surgeon, Glasgow Royal Infirmary.

THE two cases presented in these notes were different in origin, degree, and urgency; and, when considered in contrast, their clinical histories were very typical of two of the main types of obstruction of the gullet. From the surgical point of view, the difference of age, and of the probable size of the stomach, raised the question of the most suitable operation. The element of time was an important consideration, since the older patient was weakened by age, disease, and limited alimentation, and the younger one was greatly emaciated by a long period of absolute starvation. The method adopted seemed most likely to suit both patients in the matter of speed and comparative freedom from shock, and, as the results show, it was well adapted for both.

CASE 1.—*Malignant Stricture.*—J. W., æt. 70, a joiner, sent by Dr. Stevenson, of Larkhall, consulted Dr. Monro on June 23rd, 1906, and was afterwards (July 2nd) admitted to his wards in the Royal Infirmary. The principal symptom was a difficulty in swallowing, which had come on gradually in the early part of the year, but had recently increased more quickly. At first there was trouble chiefly with butcher meat and fish, while other solids and liquids went down quite well. For about a month before admission a good many mouthfuls which the patient attempted to swallow were rejected, but he never had any trouble with liquids unless he had taken solids immediately before.

He never put up sour material or blood, or anything resembling coffee grounds. He had no feeling of sickness, and he felt that he could take more food if he could get it down. The stools were natural in appearance. He had no pain, but he felt as if there were an obstruction at the level of the fifth costal cartilage. He had lost two stones in weight since his illness began. There was nothing in the history to suggest that any corrosive substance had been swallowed.

A stomach tube passed on July 3rd met with some resistance soon after it entered the gullet, but this resistance was easily overcome. The end of the tube, on withdrawal, yielded a little blood, among which large squamous cells were found. There was no evidence of secondary disease in other accessible parts. The patient was transferred to Dr. M'Gregor's care on July 6th.

Operation.—On July 7th the following operation was performed under chloroform anæsthesia. The skin incision was made almost vertically through the left rectus abdominis muscle at the level of the distal ends of the eighth and ninth ribs. The incision was carried directly through the abdominal wall. The stomach was found empty, and there was no evidence of new growths in its wall, and no tumour could be felt at the cardiac end. An abnormal mass was found under the liver, probably a secondary glandular lesion. A cone of stomach was delivered through the abdominal wound by traction on a silk suture inserted just above the greater curvature towards its cardiac end. Traction on this suture was maintained until the base of the cone was sutured to the abdominal wall. An incision was then made in the apex of the cone of stomach sufficient to admit a No. 12 (E) catheter. A strong rubber catheter was inserted and sutured to the opening by a catgut suture. The apex of the cone was invaginated by pushing in the tube, and a continuous catgut suture was employed to fix the stomach wall to the tube during the process of invagination. When the stomach had been returned as far as the sutures fixing it to the abdominal wall, the deeper parts of the wound—muscle, sheath, and subcutaneous tissue—were sutured close up to the tube. The skin was fixed with Michel's clamps. A dressing was applied, and the tube was clamped outside the dressing.

The after history was uneventful. For the first few days the patient was fed every four hours by nutrient enemata consisting of 3 ozs. of peptonised milk. About 6 ozs. of saline solution were administered per rectum at intervals. After the first day he had sips of hot water by the mouth, and feeding by the tube was begun on the third day. The skin clamps were removed on the seventh day, and the tube on the thirteenth day. The wound looked well and was dry except for a slight amount of excoriation round the tube. Vaseline and sodium bicarbonate were then used as a dressing

On July 30th, 18 days after operation, it was noted that "the patient is now feeding himself by the tube, which he introduces each time." The patient's general condition was poor, and he was rather weak. He had, however, been out of bed for some days prior to dismissal.

After leaving hospital the patient reported himself at intervals, and expressed himself satisfied that he had gained in strength. On one occasion a dressing forceps was used to stretch the opening, which had contracted slightly at the level of the skin.

CASE 2.—*Cicatricial Stricture.*—Jessie W., æt. 21, a domestic servant, was admitted to Dr. Monro's wards in the Royal Infirmary on June 15th, 1906, having drunk a quantity of ammonia after a difference with her sweetheart. She was semi-comatose and her pulse was very feeble. The skin was peeling from the lips

(a) The patients were shown at a meeting of the Glasgow Medico-Chirurgical Society, on November 16th, 1906.

and the mucous membrane from the interior of the mouth, while the tongue was bleeding. There was a good deal of albumen in the urine. She could scarcely swallow anything Three days later she was still complaining of much pain in the mouth, and along the front of the chest down to the stomach. Small sloughs were separating from the tongue. There was nothing noteworthy about the heart or lungs. She still vomited when she tried to drink anything. A week after admission she was still vomiting, though she was able to retain some milk. The vomitus included brown and green material. The maximum temperature observed was 99.8° F. on the day after admission. She was dismissed on July 3rd, to all appearance quite well.

Very soon, however, she became unable to swallow, and she was re-admitted on July 23rd. Any fluid which she tried to take was rejected in about a minute. She felt as if the obstruction were situated about an inch above the xiphoid. She also complained of weakness. On July 25th the œsophagus was examined with bougies. A moderately thick one was arrested soon after it entered the gullet. A medium-sized and a fine one were both arrested at about 10½ inches from the incisor teeth. She was transferred to the surgical wards under Dr. M'Gregor's care on the following day.

On admission to the surgical wards her temperature was 98.4° F., the pulse rate was 64, and the respirations averaged 16 per minute. The cheeks were flushed and well filled out. The eyes were clear, the pupils medium and active. The tongue was moist and slightly coated at the back. The muscles were all flaccid, but emaciation of the arms and legs was not extreme. The body was very thin, and this condition was most markedly seen on inspection of the abdomen, where the thin abdominal wall seemed to fall away from the ribs, and the iliac crests stood out with undue prominence. The eyes were deeply sunken in the orbits. The heart and lungs were normal. The urine was loaded with urates (amorphous urates and urate of soda). Neither albumen nor sugar was detected.

Operation.—Gastrostomy was performed by Dr. M'Gregor by the method already described.

Nutrient enemata were administered shortly after the operation, and were continued, with saline rectal injections at intervals, till August 1st. Alimentation by the tube was begun on the day after the operation. The patient had been troubled with nausea, flatulence, and retching, and at night morphine was given hypodermically. The Michel's clamps were removed on the fifth day, when the wound was found quite dry. From that date the patient made steady progress. The amount of fluid nourishment taken by the tube amounted to between three and four pints per diem. The tube was found loose at the next dressing, on the tenth day, and there were no signs of irritation about the wound. On that date, August 11th, an attempt was made to pass œsophageal bougies, but without success. On the following day she swallowed 10 ozs. of milk, and also some rice and milk. This was the first thing swallowed by the mouth for over a month. She continued to make progress, though slowly, in the restoration of her general health. No difficulty was experienced in the administration of food, though the quantity taken at each time was small. For about five weeks after the operation her mental condition was one of depression, with lack of interest in her own recovery, but in the early days of September she became brighter, and began to take an interest in the work of the ward, and in her own condition. On the 19th of that month she was transferred to Dr. John Macintyre's care for direct treatment of the œsophageal constriction. See Dr. Macintyre's note.

The operation in this case was very easily accomplished, though it should be remarked that the diminutive size of the stomach allowed but little choice in the selection of a suitable point for the opening An attempt was made to pass a No. 1 œsophageal bougie from the stomach to the gullet without success, and, as the patient's condition was somewhat critical, it was not deemed advisable to prolong the operation. The amount of retching and discomfort after the operation was probably due to tension resulting from the small size of the stomach, and indicates that other operations requiring a larger amount of stomach wall would have been followed by greater discomfort and perhaps lack of success.

Note by Dr. John Macintyre.—The patient was first seen in the throat wards on September 9th. A careful examination showed that no food could be passed into the stomach through the mouth. There was a great accumulation of œsophageal and buccal mucus, causing the most distressing symptoms. A small oval Mackenzie bougie could be passed to the seat of stricture, but no further. With a view to localising the upper part of the obstruction, a metal coin-catcher was passed down, and an X-ray photograph taken. This showed that the instrument was arrested at the level of the fifth dorsal vertebra.

On the 14th of the month I succeeded in passing a No. 1 Mackenzie oval bougie. On the next day the same instrument, when passed, set up irritation of the stomach, and, for the first time, the patient ejected fluids clearly coming from the stomach. Day by day the conditions were carefully observed, and as often as possible an instrument was passed into the stomach. Now and again it was necessary, however, to stop the treatment, because the slightest extra irritation caused spasm, so that at no time force was used.

For a week previous to dismissal on September 27th, it was quite evident that fluids could be swallowed; so that, within three weeks, one could say that there was distinct evidence of fluids being passed upwards from the stomach, and fluid food in small quantities downwards into the stomach. This process of gradual dilatation has been continued; but, as before, at intervals, the process has been stopped whenever there was any evidence of irritation or of extra sensitiveness.

The question of how far the process will ultimately be successful cannot at present be answered. When the mucous membrane of the œsophagus is thoroughly cleansed, and Killian's instrument for direct illumination of that organ is passed, it is seen that the mucous membrane above the seat of the stricture is fairly healthy. The cicatricial portion seems pretty well limited to a short length of gullet below the level of the fifth dorsal vertebra, because, as soon as the seat of obstruction is passed, the bougie enters freely into the stomach. At the present time the largest-sized instrument passed has been a No. 3.

The case presents many points of interest, and not the least difficult part of the treatment is caused by the present state of the stomach. Dr. M'Gregor states that at the time of operation the viscus was very much smaller than normal, and this perhaps explains, to a certain extent, the very frequent attempts at retching and vomiting with which we have become familiar since the œsophagus was opened. On one occasion castor oil, which was passed into the stomach through the new opening, and not by the mouth, was immediately ejected through the œsophagus, and, with it, bile and some liquid food which had been taken shortly before.

The process of gradual dilatation is the one which I have selected in this case, in the first place because, in similar cases in my experience, if often proves successful, and in the present sensitive condition of the œsophagus and stomach of this patient any attempt at passing a tube into the œsophagus and leaving it there would set up irritation. Whether or not it will be possible, in the future progress of the case, to pass and leave in a Symond's or other tube, cannot at present be stated, but it is to be hoped that by careful and persistent, gradual, if slow, dilatation of the œsophagus, the natural channel may further be opened up.

Remarks by Dr. M'Gregor.—The operations were almost identical in these two cases, and, for the most part, the indications given by Binnie (*Oper. Surgery*, 2nd Ed., p. 245), under the title "Stamm-Kader," were followed. The procedure is one which seems to have been evolved from the combination of more than one of the cone methods of treating the stomach, and, in addition to those mentioned, the method of Senn seems to have been a progenitor. A departure from the method as described by Binnie was made in one or

two matters of detail. The stomach was fixed in the wound by sutures at each end, which included the peritoneum and deep fascia of both sides. After these were tied, a row of continuous catgut sutures was used to fix the base of the cone of stomach to the peritoneum and deep fascia on each side of the wound. The point of the tube was next fitted into an opening in the apex of the cone, and fixed there with a continuous suture through stomach and tube. Another suture was used, spirally, to fix the remainder of the cone, during its invagination, to the tube. The stomach was infolded as far as the posterior wall of the sheath of the rectus muscle, and then the wound was closed by interrupted deep sutures right up to the tube, without the insertion of any local drain. Michel's *agraffes* were used for the skin suture.

For ease and speed of operation the above method is preferable to any of the better known methods, such as the Franck and the Witzel, or their modifications. The efficiency of the valve action in preventing leakage is excellent; the removal of the tube between meals, and its re-introduction by the patient, are easily accomplished; and the absence of a fixed tube is a great convenience. The amount of contraction after four months is small, and a No. 12 E catheter is easily passed. Recently, in another patient, a much larger tube was used, in the hope that a larger opening would be more serviceable to the patient.

TUBERCULAR ULCERATION OF THE TONGUE.

By ANDREW WYLIE, M.D., C.M.,
Assistant-Surgeon, Central Throat and Ear Hospital;
AND
WYATT WINGRAVE, M.D.,
Pathologist, Central Throat and Ear Hospital.

A. F., æt. 24, van driver, consulted me in August last, complaining of "loss of voice, great difficulty in swallowing, and pain in his tongue when eating solid food."

Patient stated that he was perfectly well until last Christmas; after that time his voice became gradually thick, rough, and hoarse. He coughed considerably at times.

About the middle of January a small "blister" appeared near the centre of his tongue, which became gradually larger until it was a deep hole. He consulted his own doctor in April, chiefly because of the pain both on swallowing and in his tongue when eating, who, in view of the ulceration of the tongue being the first and most prominent sign of disease, attributed it to syphilis, and prescribed potass. iodid. in large doses for fully three months, with no beneficial effect.

The patient gradually grew thinner, hoarser, and had more and more difficulty and pain in swallowing, as the ulceration by this time had become more pronounced.

Patient gave no specific or tubercular history. He is married, but has no children.

The man was feeble, thin, and emaciated, and when examined he could not speak above a whisper, and only swallowed with great difficulty and pain. He had a severe cough, with slight expectoration, a hectic flush, but no night sweats.

The tongue was deeply ulcerated about the middle of the dorsum. It was irregular in outline, deeply excavated with punched-out ragged edges, the floor being rough and mamillated; there was no pain in it except when irritated by food or drink.

The pharynx, tonsils, and palate were normal. The epiglottis was large and œdematous, with superficial ulceration at the edges. The arytenoid cartilages were pale and very much swollen, while the inter-arytenoid space was the seat of considerable infiltration. The vocal cords were red, œdematous and thickened. The lungs were solid at the apices, with numerous crepitant râles. The cervical glands, both superficial and deep, were enlarged. Tubercular bacilli were present in the sputum.

A considerable part of the epiglottis was removed by Barwell's punch forceps, which afforded much relief to the pain and difficulty in swallowing; for several weeks he felt considerably better, was able to swallow food with comfort, and even gained a little weight. The ulcer was touched several times with formalin 2 per cent., and seemed to be healthier, but, severe hæmoptysis taking place, the patient died about six weeks afterwards.

Dr. Wyatt Wingrave examined the sputum, scrapings of the ulcer and the epiglottis, which was excised, and reports as follows:

Fig. 1.—Tubercular Ulcer of Tongue.

Scrapings from the lingual ulcer exhibited tubercle bacilli, and the usual cell elements, together with large epithelioid cells characteristic of a tuberculous process.

The sputum also contained tubercle bacilli.

The epiglottis was deeply infected with tubercular deposit, containing giant cells and bacilli *in situ*. There was well-marked perichondritis and some ulceration extending to the surface of the mucous membrane.

Remarks by Dr. Wylie.

The tongue is not very often primarily the seat of tubercular disease. It is affected sometimes by bacilli from the sputum through some erosion. It may also be due to the breaking down of an interstitial tubercular nodule, as was probably the case in this instance. The usual character is a shallow, superficial ulceration with well-defined edges, "granulated" base, and no induration, situated on the side or top of the tongue, and does not cause much pain, except during eating, when it is acute. In this case the ulceration is deep, ragged, with indurated and uneven edges, and has an appearance like a typical syphilitic ulcer; but the presence of pulmonary and laryngeal phthisis and the bacteriological evidence left no doubt of its nature.

Fig. 2.

I report the case as being a somewhat abnormal tubercular ulceration of the tongue.

Remarks by Dr. Wingrave.

The case is of interest by reason of the striking similarity which the lingual ulcer bore to a tertiary

syphilitic lesion following breaking down of a deep gumma.

Early tubercle of the tongue is generally superficial with a mamillated base and edge occurring either at the side or tip of the oro-glossus; situations favourable to erosions from the teeth which facilitate bacillary infection. The lingual tonsil is rarely a primary seat of tubercle, being generally involved with the faucial tonsils and palate in disseminated tubercle of lungs and larynx.

The appended photograph (No. 2) illustrates an *early* (and probably primary) tubercular ulcer of the tongue, having many of the characters of a "primary" syphilitic sore. It was taken from a patient, æt. 48, who died subsequently from an accident and acute miliary tuberculosis, whose case I reported to the Pathological Society in 1893; microscopic sections of the ulcer show typical tuberculosis.

The photographs illustrate the two distinct types of tuberculous ulcer of the tongue, the early or superficial and the deep. Dr. Wylie's case belongs to the latter type, since it probably started as an interstitial or submucous tuberculoma. It further illustrates the important aid to diagnosis which an immediate examination of the scrapings affords.

THE MOUTH AS A FOCUS OF INFECTION.

By FREDERICK NORMAN, M.D., F.R.C.S.ENG., D.P.H.,

Surgeon to the Camberwell Dispensary.

IT has long been my conviction that the mouth is the hotbed of many pathogenic organisms which perform a by no means unimportant rôle in the production of certain general disease of hitherto unexplained origin, but the source of which can be traced to the oral cavity. These pathogenic mouth bacteria are so numerous and so diverse in character that it is impossible to identify them by a simple microscopic examination of the saliva. Cultures on agar-agar are not satisfactory, for many of them will not grow on this medium or are of such feeble vitality that they are soon ousted by the more proliferous saprophytes of the mouth. Gelatin is equally futile for the purposes of diagnosis, and inoculation into mice is the only reliable criterion. It is many years since Pasteur discovered in the human saliva a pathogenic micro-organism in the form of a figure of 8, and since then Miller, of Berlin, Fränkel, Gaglio and Di Mattei, Banti, Foa, and many others, have furnished contributions dealing with the toxic properties of the saliva.

When a few drops of salivary secretion are injected into the abdominal cavity of a mouse, death ensues in a few hours, or it may be in a few days, from acute peritonitis or blood-poisoning, or both. Injections with the blood, or peritoneal exudations of these animals produce the same results as injections with the original saliva. Of salivary organisms cultivated on artificial media more than a score have been isolated and identified. Amongst the most important are Fränkel's diplococcus of pneumonia (possibly identical with the organism originally described by Pasteur) the micrococcus pneumoniæ of Friedlander, and the bacillus bucallis muciferens and various varieties of bacilli sputum septicæmia. In addition to actinomyces and saccharomyces albicans (thrush fungus), the bacillus tussi convulsivæ and the bacillus bronchitidis putridæ are not infrequently detected. Many diseases may be traced to the action of the bacilli having their habitat in the mouth. I do not propose dwelling at any length on purely local diseases, but reference may be made to caries of the teeth, alveolar abscesses, and their complications, ostitis, osteomyelitis, periostitis, and necrosis of the jaw. It has been abundantly proved that "phossy" jaw, due to phosphorous poisoning, is tuberculous in origin, the immediate source of infection being tubercle bacilli, which find a gathering place in the saliva. The infectious anginæ such as tonsillitis, amygdalitis infectiosa, and their several complications are due to the localisation of germs and their entrance through the tonsils. Angina Ludovici, noma, stomatitis, and other similar conditions fall within the same category. Of other constitutional diseases with localisation in the mouth, diphtheria and syphilis serve as well-known examples.

The necessity for the adoption of antiseptic methods in all surgical operations is fully admitted, and is scrupulously enforced in all regions of the body with the solitary exception of the mouth and throat. No one seems to think of antiseptics in connection with tonsillotomy and uvulotomy, and that in spite of the fact, as has been shown, that the mouth is a receptacle for germs of all kinds, some benign and some pathogenic. It is true that in operations for the removal of the tongue for cancer, antiseptic precautions are observed, possibly from the fear of septic pneumonia, and it is safe to say that the mortality from this complication decreases in direct proportion to the strictness with which these measures are carried out. In these cases the patient is put through a preliminary course of dental treatment, all necrosed stumps being extracted and all decayed teeth carefully stopped. But still the main proposition maintains, and in the majority of operations in the region of the mouth and throat equal care is not observed. This carelessness is not readily capable of explanation, unless on the grounds that the methods by which oral sepsis can be ensured are not fully appreciated. The demand for the adoption by dental surgeons of the antiseptic measures observed in general surgery is becoming day by day more imperative.

The publication of Dr. Wyatt Wingrave's paper on "Oral Sepsis in Operations on the Throat" (*a*), forestalls to some extent certain clinical observations on which I have been engaged. My interest in the subject was excited by a consideration of the fact that we have few antiseptics in general use applicable to the disinfection of the oral cavity. The point we have to consider is what steps can be taken to prevent the growth of bacilli, pathogenic and non-pathogenic, in the mouth, with the view of limiting as far as possible the action of micro-organisms not only on the teeth and other organs of the mouth, but to keep in check those far more serious diseases which so frequently result from the want of attention to the mouth. There are many diseases of the mouth which readily take on a septic character, and although the list of mouth washes and gargles is comprehensive, there are none free from serious disadvantages. Carbolic acid and members of the phenol group are not only toxic in action, but when used over a long period exert a deleterious effect on the mucous membrane of the mouth producing in the epithelium and sub-epithelial tissues a carnification which is undoubtedly a step on the road to the precancerous stage. It is important to avoid injuring in any way the protoplasmic cells which by their function and activity resist the onset of malignant disease. Creosote, a crude mixture of guaiacol and creosol, is open to this objection. Corrosive sublimate is a violent tropical irritant producing cloudy protoplasm, so that it cannot be recommended for indiscriminate use, either in the form of a lozenge or a gargle. Permanganate of potassium is soon neutralised, and apart from its nauseous and sickly taste, has but little effect as a local antiseptic. It has the further disadvantage of staining the tissues with which it comes in contact. I have from time to time tried liquor carbonis detergens, creolin, and various other preparations, and have discarded them all in turn as being unsuited to my purpose. The essential oils, such as oil of peppermint, oil of cloves, and especially oil of cajeput, are useful intestinal antiseptics, but are unsuited for the disinfection of the mouth. Their persistent and pungent odour and taste induce a disrelish for food, and the patient soon complains of loss of appetite.

Formic aldehyde, a substance originally discovered by Hoffman, in 1869, is a more powerful disinfectant than carbolic acid, over which it has many advantages. Although destructive to micro-organisms, it is innoc-

(*a*) *Lancet*, October 20th, 1906.

uous to animals, and is practically non-toxic. From its pungent odour and taste it is by no means easy to prescribe it in a palatable form. Looking about for an efficient substitute, and one possessing equally powerful antiseptic and disinfectant properties, I tried Formamint, a definite crystalline body, a chemical combination of formic aldehyde, menthol and lactose. It is a penta-methynal lactose, having the chemical formula $5CHOH + C_{12}H_{22}O_{11}$. It is conveniently administered in the form of gramme tablets each containing 0.01 gramme of formic aldehyde. A fractional dose of citric acid is added which gives a sharp, pleasant, refreshing taste which is particularly acceptable to febrile patients, and is an advantage in the case of drugs intended to be swallowed slowly and to exert a topical action on the mouth and throat. A lozenge has many advantages over a gargle, not the least being that the mere act of sucking exerts reflexly a stimulating action both on the mucous membrane of the stomach and on the central nervous system. Mastication also increases the secretion of saliva, an abundant flow of which is necessary for preserving the sensitiveness of the nerve endings of taste. It is a somewhat curious circumstance, and one I have often noticed that children who are suckled enjoy an almost complete immunity from thrush, whilst those brought up by hand often fall victims to it.

I have used Formamint in a considerable number of diseases and morbid conditions of the mouth and tongue, of which a few only are here enumerated.

Pyorrhœa alveolaris, spongy gums, or Rigg's disease, is so common a complaint and usually runs so chronic a course that any means of alleviating the patient's suffering must prove acceptable. There is not only a spongy condition of the gums, but they recede, exposing a portion of the fangs of the teeth, which, no longer implanted firmly in their sockets, are loosened and not uncommonly drop out. The inflammation extends to the peridental membrane or periosteum of the fang, with the result that pockets of pus are formed which extend along the roots and involve destruction of the tissues of the gum and alveolus. It is said that this condition is due to the deposit of tartar from the saliva, but this explanation seems inadequate, and the disease is probably bacterial in origin, although no specific organism has yet been isolated. The difficulty arises from the presence of many varieties of micro-organisms in the mouth. I cannot help thinking that it is something more than a purely local disease, for its persistence is attended with far-reaching effects.

The constant drain even in small quantities of septic material into the stomach must be prejudicial to health. In the interest of the patient the condition should not be allowed to go on unchecked and uncured. For many years I used as a local application to the gums a mixture of equal parts of tincture of aconite and tincture of iodine, but this requires to be painted on not only frequently, but with care. Patients soon get careless about such matters, and neglect their teeth until they are so loose as to be in danger of falling out or so tender as to interfere with mastication. As a mouth wash I have used equal parts of tincture of cinchona and tincture of rhatany, but the bark is thrown down on the addition of water, and its astringency renders it anything but a popular remedy. Of late, and in a considerable number of cases, I have prescribed Formamint, and the result has been satisfactory. The constant action of an antiseptic which hardens and braces up the relaxed gums and adjacent mucous membrane gives just that amount of topical stimulant needed to restore the inflamed tissues to their normal condition. On the theory of a bacterial origin we have a ready explanation of the mode of action of the remedy.

Reverting to the subject of operations on the throat and adjacent parts, it is argued that as the mouth is the seat of much traffic, asepsis is impossible of accomplishment. That is an entire mistake, although I am prepared to admit that streptococcic infection rarely occurs. It is better to be on the safe side, and prior to an operation and after the last meal I make it a rule to direct the patient to allow one or more tablets to slowly dissolve in the mouth. Quite apart from other considerations, it occupies the mind during a period of mental anxiety and weary waiting. Wingrave points out that although it is impossible to sterilise the mouth and keep it sterile by the use of antiseptics, the risk of auto-infection during operations in its neighbourhood may be greatly reduced. It is especially in the case of anæmic and debilitated children that these precautionary measures should be observed, for it is in them that middle-ear infection follows adenoid operations.

Anæsthetic pneumonia occurs more frequently after the administration of ether than with chloroform, and in some cases may be due to the exposure of the patient to cold or possibly to the chilling effect of the anæsthetic. In more than one instance I have had reason to suspect a septic contamination of the mouthpiece of the apparatus. The risk may be small, but it is better to discount it by the use of a disinfectant, and for this purpose Formamint answers admirably. Moreover, it induces a condition of partial anæsthesia of the mucous membrane of the stomach and materially lessens the tendency to post-operative vomiting, whilst by its stimulating action on the nerve centres it wards off the effects of shock.

When patients are exposed to the contagion of such diseases as diphtheria and scarlet fever—I am almost inclined to include rheumatic fever in this category, seeing that it so frequently begins with an attack of tonsillitis—it is a wise precaution to ensure that the mouth and throat are in as an aseptic condition as possible. It is difficult to prove experimentally that this theory is sound, but there is much to be urged in its favour.

In acute tonsillitis I rely to a very large extent on the early administration of tincture of aconite in small and frequently repeated doses. As an adjuvant I use Formamint, and it certainly relieves the pain and feeling of tension in the throat. I note that Blumenthal, of Berlin, adopts the same method of local application, and that in a large number of cases, some of which he publishes in detail, he has obtained excellent results.

In cases of secondary syphilis treated with small doses of mercury, I give the patient careful directions respecting the necessity for ensuring the cleanliness of the mouth and teeth. Sometimes, however, in spite of all precautions, there may ensue ulceration of the mucous membrane of the mouth or of the tongue and tonsils. The custom is to order an astringent gargle, but, practically, a patient following his usual avocations cannot gargle when he is away from home. What is required is a continuous application—something that can be sucked in the tram or 'bus, in the office, or in the street. Lozenges of chlorate of potassium or of chlorate of potassium and borax are used for this purpose, but their antiseptic properties are slight. In Formamint the formic aldehyde is disengaged so slowly from the combination that although it exerts its disinfectant action topically the taste is covered by the menthol, whilst the citric acid braces up and stimulates the mucous membranes.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

REMOVAL OF GLANDS.—Mr. CUNNING operated on a case of recurrent carcinoma in the glands of the axilla and supra-clavicular glands in a female patient, æt. 52. A lump could be felt under the clavicular portion of the pectoralis major, the sternal portion having been removed at a first operation three years ago. Some glands could also be felt above the clavicle at the base of the posterior triangle. An incision was made extending from the left edge of the sternum to the insertion of the pectoralis major in the humerus at the level of the third intercostal space, and the skin was reflected from this both upwards and downwards.

The remaining portion of pectoralis major and the pectoralis minor muscles were then detached from their origins, and with their covering fascia, fat and an enlarged gland lying on the costo-co acoid membrane reflected outwards. The axillary vein was next exposed where it passes under the clavicle, and a careful dissection was made of the fat, and some infected glands which were surrounding this vessel. This was rendered very difficult by the fact that very dense scar tissue was present here as the result of the previous operation. The whole mass was now freed from the axillary vein and removed as one piece by detaching the insertion of the pectoralis minor from the coracoid process and the pectoralis major from the humerus. A second incision was then made at the level of the upper border of the clavicle from the inner edge of the sterno-mastoid to the insertion of the trapezius and another from the anterior end of this upwards for two inches along the anterior border of the sterno-mastoid. The sterno-mastoid was exposed and divided. A mass of glands was then exposed at the base of the posterior triangle reaching inwards to the internal jugular vein and running up along its outer side for an inch and a half. These were easily removed, and none could be felt running down towards the mediastinum. The incisions were then sutured and a small draining-tube left in each wound. Mr. Cunning called attention to the black pigment to be seen in the supra-clavicular glands. This, he said, was an unusual circumstance, and one rarely seen in recurrent carcinoma; he believed this coloration to be due to blood pigment. He also pointed out that although there were no traces of glands beyond those which had been removed, the prognosis must be grave in all cases where glands had to be removed above the clavicle. It was most likely that the mediastinal glands were also involved, though there was no evidence to that effect as yet. He considered that a perfect clearance could be obtained by this method of two incisions without dividing the clavicle. The gland on the costo-coracoid membrane was, he remarked, one which was frequently overlooked, as in a great number of cases it was never enlarged. Still, here was a case in which it was affected. This was an additional reason for taking away both pectoralis muscles so that the costo-coracoid membrane and its glands could be removed at the same time.

TRANSACTIONS OF SOCIETIES.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 6TH, 1906.

Dr. J. O. AFFLICK, President, in the chair.

DR. W. G. SYM and Mr. CAIRD showed a patient who for 13 years had suffered from proptosis of the left eye, due to intraorbital tumour. The vision was not impaired, though latterly the proptosis had attained such a degree that the eye was almost completely extruded from the orbit. The tumour had been operated on after Krönlein's method, by removing the outer wall of the orbital cavity. The result had been completely successful, inasmuch as the proptosis was cured, while full vision had been retained.

Dr. W. G. SYM showed a child after enucleation of both eyes for glioma. The patient was the second member of the family who had been thus affected.

Dr. BYROM BRAMWELL showed a case of fracture of the base of the skull, followed by paralysis of several cranial nerves. The patient was a pitman, æt. 21. On May 3rd he met with an accident, which rendered him insensible for 15 minutes, and was followed by hæmorrhage from the nose and ears, and thereafter by a discharge of watery fluid (presumably cerebrospinal) from the nose. He was completely blind in the right eye from injury to the right optic nerve, the pupil being insensible to light thrown into that eye, while the consensual reflex was retained. The eye was immovable in an outward direction from paralysis of the right external rectus. The facial nerve was also paralysed, and three months after the injury there was reaction of degeneration in the affected muscles. There was also paralysis of the left external rectus. The object of bringing the case before the society was to show that notwithstanding the complete facial paralysis with reaction of degeneration three months after the injury, a few months later complete recovery had occurred. There was now practically no facial paralysis; the blindness, however, was permanent. A case like this showed that some time should be allowed to elapse before surgical intervention in the way of nerve grafting was considered.

Mr. CAIRD showed (1) two patients after removal of nasopharyngeal fibrous polypi. The first case was a boy in whom the first symptoms showed themselves in February, 1905. In July of that year the polypus was visible in the back of the pharynx, and urgent respiratory difficulty had necessitated an emergency tracheotomy. As a preliminary to removing the tumour the common carotid was exposed, and a temporary ligature placed round it so that hæmorrhage could be controlled if need arose. The tumour was removed after excising the upper jaw, by which means free access was gained. It recurred some months afterwards, but was easily removed by opening up the old incision. It was a simple fibroma, and appeared to have grown from the body of the second cervical vertebra. The second case was a lad of 13, in whom access had been got to the tumour by splitting the palate. The same preliminary tracheotomy and ligature of the common carotid had been carried out in this case also. It was noteworthy that the removal of the upper jaw caused very little deformity.

(2) A patient with injury to the elbow and contraction of the flexor muscles of the forearm (Volkmann's ischæmic contracture). In this condition there was hæmorrhage into the muscles which resulted in a deformity simulating that caused by musculo-spiral paralysis. It generally followed injuries to the elbow joint, for which splints had been applied. In the case in question, however, the injury (a diastasis of the lower end of the humerus) had been healed without splints. The fingers were flexed, and the hand in the position of wrist-drop; the fingers could not be fully extended unless the wrist was fully flexed on the forearm. The condition was due to a contracture of the flexor muscles, and, to remedy it, it was proposed to split the tendons of the affected muscles.

(3) Specimens of nasopharyngeal polypi.

Dr. BYROM BRAMWELL read a paper on

"THE PRESENT POSITION OF THE TUBERCULOSIS QUESTION IN SCOTLAND, WITH SPECIAL REFERENCE TO THE RECENT 'CIRCULAR' OF THE LOCAL GOVERNMENT BOARD."

The speaker first referred to the economic importance of fighting a disease which destroyed so many lives at the period at which the wage-earning capacity was at its maximum. Financially, therefore, the crusade against phthisis was justifiable. During the 30 years 1871 to 1901 the mortality had diminished in Scotland from 278 per 1,000,000 to 153 per 1,000,000, but none the less there was still great necessity for a combined effort on the part of the public, the medical profession, and the public authorities, in order to deal effectively with the disease. The fall in the phthisis death-rate had occurred in all parts of Scotland, except the insular rural districts. It must also be noted that in these districts the number of uncertified deaths was excessively high, so that probably the mortality from phthisis was even greater than appeared. The persistence of a high mortality in these districts was due to the bad sanitary conditions prevailing, as had been shown in Professor Dittmar's report on the Lews. The lessened death-rate elsewhere was due to better sanitation and conditions

of life rather than to any special steps which had been taken. In connection with the crusade against phthisis in Scotland, he alluded especially to Dr. R. W. Philip's work. By far the most important step taken in recent years was the issue by the Local Government Board of the Circular of March 10th, 1906, in which it was laid down that phthisis was an infectious disease, and therefore came under the provisions of the Public Health (Scotland) Act. In regard to phthisis, there had been a great advance in public opinion within the last ten, and particularly during the last five years. On the discovery of the tubercle bacillus, the disease was recognised as being infectious, but for a long time this had led to no practical result. Recently there had been a considerable change of opinion as to the propriety of the compulsory notification of phthisis. In 1898 Dr. Thorne Thorne had delivered a series of lectures on the administrative control of phthisis, and after discussing the pros and cons of compulsory notification, had declared himself against it. His strong adverse opinion had stopped all progress in that direction for many years. Shortly after Dr. Thorne Thorne's lectures had been delivered, Dr. Byrom Bramwell had discussed the subject in an address to the Fifeshire Branch of the British Medical Association, and had tried to prove that the arguments of the former were not valid. At that time, however, he met with little support. Seven years later the Fife Branch adopted a unanimous resolution in favour of compulsory notification. Last summer Glasgow adopted the practice, and he hoped it would soon become universal throughout Scotland. Coming now to the circular of the Scottish Local Government Board, which, as he said, he welcomed as the most important step in the administrative control of phthisis yet taken in the country, he thought that it was open to criticism in that it did not sufficiently emphasise the differences between the infectivity of phthisis and the infectivity of such other diseases as scarlatina, &c. In phthisis infection took place through the sputum only, and therefore could be controlled by disinfecting the sputum. In order to effect this administratively, compulsory notification was essential. Hitherto the attention of public health authorities had been limited to measures of general sanitation; now the great aim should be to disinfect the sputum, and he wished to emphasise the point that if this was efficently done the risk of infection of healthy persons was comparatively trivial. There was therefore no need for isolation. For this reason Clauses 59 (public conveyance clause) and 57 (school clause) of the Public Health (Scotland) Act, 1897, were far too drastic as applied to phthisis; these clauses should therefore be amended by a special Act. All that seemed necessary was to insert into these clauses the same *qualification* which is inserted into Clause 56, viz., "*wilfully* exposes himself *without proper precautions*." The legal question might arise at present whether a person suffering from phthisis, who destroys or disinfects his sputum (in other words, renders the infectious disease, phthisis, in his particular case, non-infective) could be convicted and fined under Clause 59. Dr. Bramwell argued that to extend these clauses to the special infection of phthisis was an unnecessary and harsh action, and that to do so would so alarm the public as to delay the coming of compulsory notification. The Hotel Clause (51) was also open to the same objection. Another point in which the circular of the Local Government Board was somewhat unfortunately worded was in the paragraphs relating to compulsory notification. These were to the effect that the Board was only prepared to consider favourably any application by a local authority to schedule phthisis among the compulsorily notifiable diseases if they were satisfied that the local authority was prepared to take steps to combat the disease effectively. Compulsory notification, *per se*, has, the Board stated, no administrative value. Dr. Bramwell pointed out that the compulsory notification Act was quite distinct from the Public Health Act, and that notification neither increased nor decreased the responsibility of the local authority under the latter Act. The speaker, however, understood that the wording of the paragraph in question did not accurately convey the intention of the Board. Notification was, of course, essential as a preliminary to taking any further steps. The Board had not intended to insist on the creation of curative sanatoria. They rather suggested the advisability of local authorities combining for the purpose of erecting such and equipping them specially for the treatment required. Dr. Bramwell concluded his address by again expressing his opinion that the clauses referred to are too drastic to be applied to phthisis, and require to be amended.

The paper gave rise to an animated discussion.

Dr. R. W. PHILIP said it was unnecessary to reiterate views which he had frequently taken occasion to express as to the great significance of the circular of the Local Government Board. There could be no doubt that the circular represented the highwater mark of official statement throughout the world on the subject of pulmonary tuberculosis. The authoritative declaration on the part of the Board that pulmonary tuberculosis was an infectious disease within the meaning of the Public Health (Scotland) Act, 1897, marked a great forward advance. On that account he would have been glad if Dr. Bramwell had prefaced his proposed motion with an expression of the Society's cordial approval—or, if it seemed more acceptable to the members, the Society's general approval—of the circular. It was a matter of congratulation for Scotland that a problem of considerable obscurity and difficulty had been cleared up by the issue of a statement at once definite and authoritative.

Dr. LAWSON (Banchory) spoke strongly in favour of compulsory notification. He alluded to the fact that the sputum of a patient might on one occasion be swarming with bacilli, and the next day be free from them. It had been proved that even when the organism was absent from the sputum, gelatine plates could be infected by coughing. He therefore considered that there was an element of risk even when the sputum was disinfected, and did not consider the provisions of the act too stringent.

Dr. NASMYTH (Fife) said the difficulty Dr. Bramwell alluded to has been a source of anxiety to him; but an explanation by the Local Government Board that it was not imperative to enforce the clauses harshly had relieved him.

Dr. DOUGLAS (Cupar) criticised the circular, in that it did not allow compulsory notification unless the local authority was prepared to deal further with the disease. Speaking as a medical officer of health, he said he could do nothing to prevent, say, a tuberculous dairyman selling milk, unless he had legal proof that he was phthisical, and this proof could only be furnished by compulsory notification. Without compulsory notification, he argued, no steps could be taken.

Dr. MATHESON CULLEN (Convener of Edinburgh Public Health Committee) thought that the clauses in question constituted no real danger. They were only carried into effect on the initiative of the medical officer of health, and comparatively few convictions had been obtained under them in regard to any infectious disease. They were only put into operation in flagrant cases, and he thought that they might safely trust to the discretion of the medical officer of health that they would not bear harshly on tuberculous patients; while, on the other hand, it was not a bad thing to have something of the kind to fall back upon.

Dr. NORMAN WALKER said he supposed that the way of dealing with the tuberculous would resemble that adopted in the case of leprosy in Norway—patients who took precautions were not isolated; those who refused to do what was right, or were unable to do so, were segregated.

Dr. BRAMWELL, in his reply, stated that he quite agreed that it was not the duty of the public authorities to cure, but to prevent disease. While, therefore, isolation hospitals for advanced cases were justifiable and necessary, the propriety of erecting curative sanatoria at the public expense remained an open question.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

President: J. F. O'CARROLL, M.D., F.R.C.P.I. Sectional Secretary: PROFESSOR WHITE, R.C.S.I.

MEETING HELD FRIDAY, NOVEMBER 23RD, 1906.
The PRESIDENT in the Chair.

PATHOLOGICAL EFFECTS OF RONTGEN RAYS ON ANIMAL TISSUES.

DR. HARVEY reviewed the main steps in the investigation of Röntgen effects since the discovery of the rays in December, 1895. He described Holzknecht's pastilles as the first attempt to measure the quantity of radiations employed, and showed how their employment led to definite laws concerning skin reactions. Passing on to the mode of action of the rays he mentioned Scholtz's view that epithelium is primarily affected, and those of Baermann and Linser and Gassmann, who hold that the effect is chiefly upon the vessels, and detailed the chief experiments of these authors. As to the actual agent causing dermatitis, the author held the Röntgen-rays themselves responsible, and favoured the trophoneurotic theory, and mentioned some original experiments on the effect of vasomotor disturbance on the phenomena. He quoted the experiments of Perthes, Dalous, and Lasserre as favouring a definite selective absorption. Coming to internal organs, he mentioned Heineke's experiments on the spleen, and those of Aubertin and Beaujard on the blood cells. With regard to the question of a Röntgen leucotoxin, he related the findings of Helber and Linser, and Curschmann and Gaupp on the one hand, and those of Kleineberg and Zoeppritz on the other. Lepine and Boulard's experiments on metabolism of glycogen were also mentioned. Albers Schönberg's classical experiments on the generative organs were recounted, as were those of Halberstaedter and others. Having mentioned some clinical features of X-ray treatment of pathological interest, Dr. Harvey spoke of his own experiments, showing microscopic and lantern preparations. The animals operated on were rabbits and guinea pigs, and the organs chiefly examined were the spleen, ovaries, testicles, and suprarenals. The experiments, which are in a preliminary stage, so far support Heineke's results in regard to the spleen. The germ centres of the Malpighian corpuscles were observed to be the first to suffer. Chromolysis and diffuse nuclear staining are present in most of the sections, and affect chiefly the young and proliferating cells. Vaso-dilatation and congestion are also common. The ovarian and testicular changes were similar to those described by previous authors. Dr. Harvey found congestion and hæmorrhages in the suprarenals of all animals subjected to X-ray treatment.

Dr. STEVENSON mentioned vesication as occurring in lupus in an area of the skin which had previously been exposed to the Finsen light. The application of the X-rays had made the skin react at that particular part, while there was no vesication or marked reaction in the surrounding parts.

Dr. WALTER SMITH considered the paper of great general interest from the point of view that such pathological observations bridged over the interval between normal physiology and therapeutics which might be called applied physiology. Broadly speaking, they might regard the action of Röntgen-rays and the like as an act of stimulation; but they need not attempt to distinguish too narrowly between the phenomena of excitation and depression, since they were but quantitative opposites which followed from continued application of the same stimulus. The nature of the Röntgen-rays had long been a puzzle to physicists. Now, however, it was agreed that they represented ethereal pulsations, and did not correspond in any way to a molecular bombardment. In discussing the physiological or pathological action of the rays, he thought it was impossible to form any satisfactory conception, unless they also took into consideration other therapeutic agencies with which they were familiar, such as the Finsen rays or radium. It was, he thought, rather unfortunate for students that the word "ray" had acquired two different significations. It retained its old meaning of undulatory vibrations of the ether, and was also applied to a direct stream of particles like the hail of tiny projectiles from radium. To get at a satisfactory explanation of the phenomena would require a thorough knowledge of the effects of all sorts of vibrations of different wave lengths, not only on animal, but on vegetable, tissues, distinguishing between the action on the higher and lower forms of vegetable life. The first indication of the therapeutic value of the rays arose, about 1900, out of the observation of their depilatory effect; it was premature to expect a coherent or fully satisfactory statement at the present time.

Dr. C. M. BENSON said that he had been handed over patients who had been treated for lupus by the Finsen light, and in his experience there had been no formation of vesicles.

Dr. SCOTT congratulated the Section on Dr. Harvey's contribution, which fixed certain points from which they could advance further. They knew certain tissues on which the rays acted; they might act on others; but that they should act on tissues of such a peculiar nature as the spleen and on the growing cells of epithelium would suggest that possibly growing cells were affected by the rays as they were by differences of acidity and alkalinity.

Dr. KIRKPATRICK thought they were perhaps frightened by the bugbear of permanent baldness in using the rays. He knew of a case of a woman in which depilation was produced, and after some months the hair grew more vigorously on her face than before the treatment.

Dr. HARVEY, in reply, said he had read of the X-rays being considered a cause of abortion. It would seem possible that they should have such an effect, as they seemed to show a greater effect on young and actively developing cells than on adult ones. His explanation as to what caused the death of the guinea-pigs in his experiments was that the X-rays caused a degeneration of cells, whereby a toxic product was liberated which killed the animals. The toxic effects of the rays had been observed in several cases, and he was in the habit of seeing that patients undergoing the treatment for malignant disease should take aperient medicine. The epithelium of the skin was not at all as sensitive to the action of the rays as that of the testicles or ovaries or spleen.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD ON MONDAY, DECEMBER 3RD.

THE following were elected as Officers and Members of Council for the ensuing Session, 1906-1907. President: Alphonso Elkin Cumberbatch. Vice-Presidents: Arthur Henry Cheatle, John Middlemass Hunt, Adam Brown Kelly, Richard Lake. Honorary Treasurer: Edward Law. Honorary Editor of Transactions: Walter Jobson Horne. Honorary Librarian: Laurence Asher Lawrence. Council: Frederick William Bennett, Charles Herbert Fagge, Joseph Nelson, William Permewan, Hunter Finlay Tod. Honorary Secretaries: Henry Secker Walker, Ernest Blechynden Waggett.

At the Annual Dinner held on the evening of the same day the President, Mr. A. E. Cumberbatch, occupied the chair. After the usual loyal toasts Dr. Frederick Roberts proposed "The Otological Society," coupled with the name of the President, who responded. Mr. Cresswell Baber proposed "The Guests." The toast was responded to by Sir James Reid.

DR. LAPPONI, the Pope's physician, died on the 6th inst., at the early age of 54. For over 15 years he had acted as Papal medical adviser, most of the time to Pope Leo XIII. For some time past he has suffered from cancer of the stomach.

UMBILICAL HERNIA IN INFANTS.

INFANTILE umbi ical hernia is in general benign and has a tendency to get well s ontaneously, or, at least, without surgical interference. It seems, however, to be more f equent in premature children, according to Professor Broca, and for this reason the umbilicus should be particularly seen to after the cord is detached.

Generally speaking, the hernia appears a few days after birth, a bandage is prescribed, and in a few months the hernia disappears.

But it happens sometimes that matters are a little more complicated, and then the prognosis is not so simple. The complications depend on the cause, the date of the appearance of the hernia, its progress, the state of health of the infant, and its social condition.

Frequently the cause is to be found in st:umous diathesis or in premature birth. In the first case the consolidation of the umbilicus is hindered by the flaccidity of the abdomen, and the hernia will not disappear spontaneously unless the food and hygienic conditions are improved. In the second, a spontaneous cure depends on the manner in which the chil l is nursed. If by the mother, the chances are that the infant will grow up normally, but if it is sent out to nurse or artificially fed, the hernia will probably not recede, if the child does not die itself.

The younge· the child, the more chances has the hernia to get well spontaneously; the older it is the more surgical treatment will be necessary.

During the first months of life, the umbilical ring commences to cicat ise, and the elements of which it is composed are being gradually transformed into compact fibrous tissue narrowing more and more the opening. On the other hand, according to Professor Berger, the calibre of the intestines increases while that of the umbilicus diminishes, until the aperture is completely closed. At the age of eighteen months or two years, the consolidation is terminated. If on the contrary the orifice remains as it is, the intestine escapes through and the tendency to spontaneous cure diminishes.

As to the mode of development, a hernia which remains small gets well without interference; but if it is comparatively voluminous and becomes irreducible at times, if the omentum penetrates it in too great abundance, the hernia will not recede spontaneously.

Besides, it may get well to all appearances, but it is only in appearance, and later on in adult life, especially in women, when pregnancy weakens the walls of the abdomen, it will re-appear with all the gravity of adult hernia. Adult umbilical hernia, says M. Berger, is frequ ntly nothing else than infantile hernia which had appeared to get well, but had returned after many years.

The prognosis of umbilical hernia depends a'so on the state of health of the child. If it is in good condition, fed properly and not weaned, every chance is on his side. If, on the contrary, he is given as soon as he is able to sit at table with his parents, meat, wine, potatoes, cabbage, etc., to "make him strong," the chances are that rickets will set in and compromise considerably the cure of the hernia.

Acute affections eruptive fevers which weaken the child, bronchitis, pneumonia, exercise an unhappy influence by attacking the general condition and provoking cough.

BLUE LIGHT.

The employment of blue rays as an agent of hypnotism was tried for the first time by Dr. Redard, of Geneva. M. Cavalié, of Borde ux, explains how to operate to obtain from this new method the best results.

An electric lamp of sixteen candles, of which the glass is intensely blue and as pure as possible, should be procured. The patient should be prepared for the experiment by assuring him that he will not be put to sleep, but momentarily deprived of feeling. The confidence of the patient is an important condition of the success desired.

The person to be operated on is seated in an armchair, and the lamp, furnished with a good reflector, is placed at a distance of four to five inches in front of his eyes, and a blue calico covering thrown over his head and the lamp, so as to prevent the daylight from penetrating.

The patient is enjoined to fix his eyes strongly on the blue lamp for two or three minutes, when his face will turn pale, and the pupils dilate. The patient seems to have fallen into a trance. It is at this moment that the operation should be commenced and rapidly terminated, as the insensibility only lasts about thirty seconds. Frequently the patient is surprised to have felt no pain from the operation, although he was not put to sleep as he had expected.

This method is admirably suited to the extraction of teeth, and is, of course, entirely free from danger.

M. Cavalié had operated thus already forty times, and almost always with success. The few unsuccessful cases were attributed to the want of confidence of the patient or a fault in the way of fixing the eyes on the blue lamp.

THYMOL AND APPENDICITIS.

Professor Guiart, affirming that appendicitis is almost always of parasitic origin, esteems that it can be cured by a simple vermifuge. He recommends thymol in large doses followed by a saline purgative, and has always obtained a cure by this treatment, which is applicable to every case of appendicitis.

The thymol is given in 15-gr. doses three times a day during three days, after which a purgative is given. The thymol is given in wafers, and the patient is ordered to drink only water during these three days. It is well accepted by the patients, who can continue their ordinary mode of living after the fourth day.

In severe cases M. Guiart gives the thymol every hour for two or three doses.

The patients are forbidden to use for a week, oil, glycerine, acetic acid, chloroform, ether, and particularly alcohol, as thymol is soluble in these liquids and poisoning might result from its absorption.

The treatment can be applied to typhoid fever and all kinds of intestinal wounds.

GERMANY.

Berlin, Dec. 9th, 1906.

THE INFLUENCE OF GASTROENTEROSTOMY ON ULCER AND CARCINOMA OF THE STOMACH.

THE discussion on Hr. Katzenstein's paper on this subject was resumed by Dr. Biekel, who remarked that the cause for the differences of effect from gastroenterostomy in the human subject and in dogs must still be investigated; possibly the difference in position played a part. Examination of a large number of cases made it probable that the disturbance present in ulcer of the stomach did not depend so much on the percentage of hydrochloric acid as on an increase in the normal acid juices.

Hypersecretion might be combated by (*a*) alkalies, atropine, and other poisons; and (*b*) by regulation of diet. He had caused comparative investigations in regard to the secretory effects of different forms of diet to be made by Frau Robinowitsch. A mixture of butter, sugar, and white of egg appeared least to excite secretions. The indications for gastroenterostomy for ulcer should not be widened. In acute hæmorrhage there might be no ulcer, the bleeding being perenchymatous. He related two cases of this kind. The frequency of ulcer had also diminished recently, as shown in the Charité statistics. In 1,399 sections three were only two cases of ulcer, but thirty-four of carcinoma.

Hr. Elsner held Hr. Katzensten's investigations to

be of extraordinary value. He related a case in which, after gastroenterostomy, an ulcer of the jejunum developed from the action of the gastric juice, the symptoms from which did not disappear even after a second operation. Here, perhaps, the diet of fats and carbohydrates recommended by Katzenstein would have resulted in an increase in the pancreatic secretion, and compensation. He thought that in carcinoma of the fundus life might be prolonged by operation by relief afforded by perist.lsis.

Hr. Fulda was of opinion that Katzenstein's investigation had contributed to the enrichment of our internal treatment by the administration of the secretion of the small intestines and by the dietetic prescriptions. They would scarcely lead to the frequent employment of gastroenterostomy. In England it must be borne in mind that gastroenterostomy was not so frequently performed for gastric ulcer as formerly. The result mentioned as regarded carcinoma depended not infrequently on self-deception.

Hr. Fedo Krause thought the whole material of a hospital presented a truer view than selected cases, and he would mention those of the Augusta Hospital. During the six years of his activity in Berlin, himself and his assistant had performed 213 operations on the stomach. A not inconsiderable number of the cases were in such a condition that the operation was of vital importance. In such cases there was no longer any question of gastric function. The pylor s was closed, or nearly so, by carcinoma, by firm cicatrices, and infiltration resulting from old ulcers. In cases of chronic ulcer with repeating hæmorrhages, or in the case of the rarer profuse hæmorrhage, observation and waiting on the adoption of any other treatment than operation was impossible. In such cases the prognosis was naturally bad. Without procuring a well-acting new connection between the stomach and jejunum, these patients were irretrievably lost.

Amongst the 218 stomach operations were 142 gastrostomies—87 for carcinomatous occlusion of the pylorus, 55, for ulcer and its sequelæ. A diagnosis as to whether the case was one of cancer or extensive cicatricial infiltration was not always possible, even after opening up and examination of the diseased organ. A case might therefore be put into the wrong category. But as such an error of diagnosis would be just as frequent in the case of carcinoma as in cicatricial infiltration, the figures given would scarcely undergo any change, even if a microscopic examination had been made in every case.

Of the cases operated on for carcinoma, 41 (=47 per cent.) died; of those operated on for ulcer only 5 (=9 per cent.) died. The more frequent cause of death was cardiac failure, and the *post-mortem* examination almost always revealed brown atrophy. The second most frequent cause of death was inflammation of the lungs; peritonitis could be avoided by careful asepsis.

The high mortality in cancer was due to the wide-reaching indications. In very feeble cases he considered operation justifiable, otherwise the patient would not die of cancer, but from starvation. As regarded results in cancer cases, an increase in weight of 20 kgrm. and over had been observed, and a number of the cases had been able to return to work. That tumours grew less rapidly after all sources of irritation were removed could not be disputed.

The permanent results of the operation on the ulcer were thoroughly satisfactory, sometimes even surprising. Peptic ulcer was not so common that it need be looked upon as a danger. The speaker had met with two cases, and they taught that strict dietary was necessary, and that if there was hyperacidity it must be overcome.

Hr. Litten said that hæmorrhage might be caused by disease of the liver, cirrhosis, or syphilis, and these conditions could not always be diagnosed, and years ago he had indicated varices in the lower part of the œsophagus as sources of hæmorrhage. The occurrence of capillary hæmorrhage had been disputed, but he had now seen two cases in which the bleeding was of this character.

Hr. Ewald said that acidity of the stomach could only be estimated as to percentage, not actua quantity.

Hr. Katzenstein, in reply, said that trypsin did not act in a strongly ac d solution. The acidity of the stomach should be tested an hour and a half to two hours after the test breakfast.

The difference of posture of men and dogs had nothing to do with the secretion. Peptic ulcer could be avoided by following the speaker's rules as to diet. He had no intention of widening the indication for operation. but where internal treatment could not succeed, the surgeon should come in. By testing the cardiac function in the way proposed by himself, cardiac collapse could be avoided; the operation could be postponed until such time as the heart was strengthened, or no general anæsthesia should be e mployed, or æther narcosis in place of chloroform.

AUSTRIA.

Vienna, Dec. 9th, 1906.

A MUSCULAR ARTIST.

At the "Gesellschaft," Haberer showed a man, æt. 32, with a wonderful power over his muscular system. By an effort he could place all the small intestine to one side of the abdomen or the other at will. He could throw all the contents of the abdomen under the diaphragm, or into the pelvis, resembling a female in the last month of pregnancy. By the same contractions he could pass waves along the abdomen like a worm, or make the sternum bend in like a cobbler's breast, or pigeon-like, resembling the strumous. With the sternothyroid and hyoid he could produce goitre; move the heart from one position to another; spontaneously dilate the pupils; and compress the subclavian artery and obliterate the radial vessels.

Altogether he thought this would be a dangerous patient to treat in critical circumstances.

SCLERODERMA.

Neurath showed a child, six weeks old, with an elastic swelling, which commenced about the end of the first week after birth. It affected the lower extremities, and ceased sharply at the umbilicus. The breast and shoulders, as well as the arms, except at the distal extremities, were perfectly normal. The latter changes commenced a few days ago. The face has also a slight puffiness. The œdematous parts were thick and firm with a porcelain appearance, but never cyanotic. At first it was white or yellowish red, cool, and without any folds. Strong pressure with the point of the fingers produced a very slight depression. This thickening was greatest on the instep, calf of the leg, scrotum, and penis.

INFANTILE SCORBUTUS.

Escherich presented two children with what he termed Barlow's disease. Neither of the children had the morbid condition fully developed, but the early symptoms were undeniable, hæmaturia being specially diagnostic. In both cases the point of special interest was the malnutrition, although the food provided had been ample and sufficient. The clinical phenomena resembled the disturbed metabolism met with in rachitis, though the increase of the skeleton portion resembled the scorbutic state of the adult, which was supported by analogous changes in the blood. Escherich thought this was not exactly a case of scorbutics, but rather one of Barlow's disease, as the change of diet alone produced a rapid improvement in the child's health.

OSTEOMALACIA.

Katholicky showed Röntgen photographs and microscopic preparations of a case of osteomalacia resembling Paget's disease. From the symptoms and preparations of the bony structure, he doubted whether it was Paget's osteomalacia chronica deformans hypertrophica or Recklinghausen's ostitis deformans fibrosa. Kolisko thought the difference lay in the inflammatory changes with the hyper-ostotic bony thickening. Latzko differed from this opinion, and thought that the

pathological change in the bone was not sufficient, but that the anatomical etiology should determine the difference. Paget's ostitis and Recklinghausen's deformans with the tumour formation were altogether different processes. In the one giant carcinomatous cells, in the other pure osteomalacia. He thought the case presented was one of Recklinghausen's simple osteomalacia deformans. Sternberg had histologically examined the cases, and found no sarcomatous cells. Kolisko thought the giant carcinomatous cells an unsatisfactory quantity, as many cases healed spontaneously when these were present. Habera always found the diagnostic carcinomatous cells on the cystic enlargements of the tumour.

HUNGARY.

Budapest, Dec. 9th, 1906.

On the 15th and 17th of this month there was held, at Budapest, in connection with the meeting of the Hungarian medical societies, a first National Congress of Cancerous Diseases. The opening meeting took place in the building of the University, where Professor Dr. Dollinger received the guests, who came together from every part of Hungary. Dr. Dollinger began the formal business of the Congress by delivering an address dealing with the occurrence of cancer among the working-class. This disease, although visiting royal houses, too, is most evident in the poor classes (owing to the want of cleanliness, perhaps), and is popularly supposed to be confined almost entirely to persons who live in crowded houses in bad hygienic conditions. This fact favours the correctness of the theory of the communicability of cancer.

In 1904 cancerous patients were conscripted in Hungary, and as the Statistical Bureau stated, there were 3,570 living cancerous patients in that time. But this number is not reliable; actually, there were many more than that.

Speaking about the treatment of superficial cancers, he said that he favours early excision, or, if the patient comes in a later stage, the application of a ray of sufficient intensity for a sufficient length of time. This is capable of causing a disappearance of the tumour and carcinomatous cell nests and their replacement by connective tissue, a proliferative, obliterative endarteritis, and a sclerosis of the lymph vessels and glands leading from the affected part. A course of radiation not to exceed ten treatments of twenty minutes each, at a tube distance of eighteen inches, is sufficient in the majority of cases to accomplish the desired results.

He ended his paper with the emphasising of the necessity of early diagnosis, and on the basis of this early operation. It is a shame to every family doctor to wait and allow a cancer case under his care to go on to the inoperable condition.

Dr. Alexander Korányi discussed the

Early Recognition of Cancer of the Stomach, and its Treatment.

He said that there is no truthfully recorded example of a cancer of the stomach cured by medical means, yet these cases are treated by medical men, and are sent into the medical wards and subjected to treatment which must result in 100 per cent. mortality. Cancer of the stomach is the most frequent form found in the human body, at least 30 per cent. of the total, a tremendous sacrifice of human life almost without effort at cure. The past high mortality of radical excision and the difficulty of early diagnosis, are largely to blame for this state of affairs. Since 1900 great improvement in technique has lowered the mortality to less than 10 per cent., and exploratory incision in the suspicious cases gives the diagnosis. If more internists saw operations upon cancer they would advise operation sooner than they do. The ordinary methods of diagnosis are not especially effective or certain for early dagnosis, though the absence of hyperleucocytosis after digestion, and the presence of lactic acid are helpful. Careful examination of the vomit may be pathognomonic. Indigestion is not always a surgical disease, neither is it always a medical disease. Persistent symptoms from the gastro-intestinal tract mean serious involvement of the gall bladder, the pancreas and the stomach, in nearly every case. It is important then, for the pysician to insist on consultation with the surgeon if the symptoms persist after careful treatment for some time.

Besides these, there were several dissertations held on the ætiology, histology, and the treatment of cancer.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Election for the Direct Representation of Scotland on the General Medical Council.—The result of this, as officially announced has given Dr. Norman Walker a substantial majority over Dr. Bruce Dingwall, the sitting representative. Dr. Walker has worked hard for, and deserved success; we doubt not that he will do excellent work for the profession on the General Medical Council.

Epidemic of Conjunctivitis in Aberdeen.—Considerable anxiety is being caused the sanitary and educational authorities of Aberdeen by the extensive prevalence of conjunctivitis among the children of the city. The matter has been brought prominently to public notice through letters to the press from the pen of Dr. Galloway, insisting on the responsibility for this state of matters resting on the School Board, who have not, he thinks, taken adequate precautions against the dissemination of the infection in the schools. The epidemic seems to have been going on for nearly a year, and attained its greatest severity in August and September. The best way of dealing with the epidemic is now under the consideration of a committee of the School Board, who seem, not unnaturally, to resent Dr. Galloway's action in writing to the press without previously laying the matter before the school officials. In a letter dated November 20, addressed to the clerk, Dr. Galloway states that at the Dispensary six new cases of trachoma had appeared during the past two days. Dr. Galloway suggests that the Board should send a clerk to the Dispensary to take names and addresses of children while the epidemic lasts. The occurrence of trachoma is a sufficiently serious matter to warrant active measures being taken, and now that public attention has been drawn to the matter, it is probable that the epidemic will soon be overcome.

LETTERS TO THE EDITOR.

MEDICAL EVIDENCE IN LAW-COURTS.

To the Editor of The Medical Press and Circular.

Sir,—It is difficult when we are giving evidence in a Law Court or before a Commission to create the impression amongst the jury or the members of the Commission that we are independent of all influence or interest but that of accurate observation. A witness can rarely be regarded as wholly disinterested on one side or the other. In your article on Slate Quarrymen and cardiac dilatation (December 5) you have taken the view that it would be well to leave the matter in the hands of "practitioners capable of throwing a deal of valuable light upon the question"; and as it requires a good pathologist to deal with it from a medical and pathological point of view, you can understand how little inducement there is to submit our clinical observations to a jury or committee of ignorant if not prejudiced laymen, whose knowledge of matters medical is often ludicrously childish. Up to the present time I have personally dealt with the subject in the usual clinical manner, observing the symptoms and various organic derangements presented in the cases. It remains now to work out the relations between conditions and causes; and it is

clear that the latter vary much among the quarrymen in Wales, from the variety of the work they are engaged in. This opens up, of course, a desire to know and see how the various kinds of work in stone and slate vary in their effects on the bodies of the men who follow them, and I hope that your article will lead to more useful inquiry into this part of the subject.

I am, sir, yours truly,

ROBERT LEE,

Pwllheli, December 8, 1906.

OBITUARY.

FREDERICK ABELL HUMPHRY, F.R.C.S., L.S.A.

WE record with sorrow the death on December 3rd of Mr. Frederick Abell Humphry, F.R.C.S., who formerly had a large medical practice at Brighton, and resided in Marine Parade. Mr. Humphry, who was 76 years of age, moved to Crowborough some years ago, and took interest in everything that concerned that health resort, but he did not himself actively engage in public matters. Mr. Humphry was educated at Cambridge University and St. Bartholomew's Hospital, and took the M.R.C.S. and L.S.A. in 1853. After holding the post of house-surgeon to the latter institution, he took the F.R.C.S. in 1856, and subsequently went into practice at Brighton. For many years he was surgeon to the Sussex County Hospital, and enjoyed a large practice.

RASHLEIGH BELCHER, L.F.P.S.Glasg.

WE regret to announce the death at his residence, Garston, Liverpool, on Wednesday evening, of Dr. Rashleigh Belcher, a well-known medical practitioner. Dr. Belcher was 58 years of age, and settled in Garston about twelve years ago as partner to Dr. Haythorne, whom he subsequently succeeded. About three weeks ago he caught a severe cold, but did not take to his bed till a week ago, when bronchitis set in. Subsequently he appeared to be recovering, but on Wednesday morning he had a relapse, became unconscious, and died shortly afterwards. He leaves a widow and son and daughter to mourn his loss.

ARTHUR GOODWIN, M.R.C.S.I.

WE regret to record the death of one of Hanley's oldest medical practitioners in the person of Mr. Arthur Goodwin. Mr. Goodwin contracted blood poisoning about twelve months ago, and since that time had always been in indifferent health. He practised, however, up till a few weeks ago, when cystitis, a painful malady, caused him to take to his bed. Mr. Goodwin went to Hanley from the Chesterfield district of Derbyshire, and had been in practice in the borough about 35 years.

SPECIAL ARTICLES.

THE MEDICAL MAN AS SOCIAL REFORMER.

When some future Buckle comes to write the history of civilisation in the nineteenth and twentieth centuries, one of his duties will be to chronicle the actions of the medical profession as an agency, direct as well as indirect, in social reform. For the most conspicuous example of this we must look to Russia. The Zemstvo doctors and their work are the great glory of Russian medicine of to-day, beside which even the epoch-making researches of Pawlow pale. The emancipation of the serfs was the signal for thousands of devoted men and women going to spend their lives as physicians among the most degraded peasantry in the world, with the avowed object not of earning a livelihood; but of spreading enlightenment and improving the conditions under which the moujik lived. Oppressed by the governing class as instruments of the hated reform, thwarted, persecuted and sometimes even massacred as the causes of pestilence by a superstitious people, these men and women suffered martyrdom only to see new comrades step into the gaps in their ranks, and now much of the improvement in the conditions of the masses in Russia must be ascribed to the work of the Zemstvo doctors. To come nearer home, and happily to far less tragic circumstances, we find the same thing happening. In the remoter parts of Ireland and Scotland we every now and then hear of self-sacrifice no less than that of our Russian colleagues. We know too, that in every peasant community the doctor, with his scientific outlook, is the reformer as well as the physician. Dr. Lachlan Grant, whose name came prominently before the public in connection with the Ballachulish dispute, in which his manly fight for the rights of his patients excited general sympathy, has, through his outspoken utterances in favour of social reform in the Highlands, been instrumental in founding a "Highland Crofters' and Cottars' Association," whose objects are to assist in the industrial development of the country, to arrest depopulation, and, collectively, to promote the interests of the people. A medical journal has no politics, and the main objects of the association depend for their attainment on political means. The nationalisation of the land, for instance, is a thorny subject, and on this and other parts of the Association's programme we naturally express no opinion. But, when it comes to medical matters, there we see eye to eye with Dr. Grant. It is quite notorious that medical officers of health are hampered by unprogressive local authorities, and that, rate and tax as you may, a poor locality simply cannot find the money needed for efficient sanitary administration. Moreover, sanitary administration urgently requires to be compulsorily extended so as to include the physical inspection, and, where necessary, the feeding of school children, particularly in sparsely populated districts. Again, some system of State medicine seems imperatively demanded in the outlying districts of the Highlands. As we have said, apart from the obstacles arising from innate conservatism, the financial difficulty in poor, sparsely populated districts is under present conditions insuperable. Somewhere or another, Mr. H. G. Wells wrote an admirable paper on Larger Administrative Areas, which went very much to the root of these questions. The present areas of administration are really relics of a past age when means of intercommunication were few. Now, with improved transit, the whole country has become much more homogeneous. In the case in point, it can hardly have escaped any observant sojourner, say, in Inverness, that the Highlander looks to London as his trading centre rather than to Edinburgh or Glasgow, and in the Highlands during the summer, even in the most remote parts, you will hear the soft southern accent nearly as frequently as the Gaelic. We have to realise that the efficiency of the nation depends on the prosperity of its individual communities. The Highlands are the playground of the dwellers in cities, who go there to gather health for the strenuous life of the town. The towns, on their part, draw from the manhood of the country the replenishment they need. Stated thus, there seems to be a good case for a more uniform distribution of burdens—for that, after all, is what State aid means.

VITAL STATISTICS IN IRELAND.

THE report of the Registrar-General for Ireland for 1905 (*a*) has recently been issued, containing as usual a well-arranged summary of the work of the Register Office during the year. The Registrar-General again acknowledges his indebtedness to Dr. Ninian Falkiner, the Medical Superintendent of Statistics, for his aid, and medical readers will agree that the information of special interest to them has received a due amount of attention.

The report has again to admit a decrease of population. The estimated population in the middle of the

(*a*) "Forty-Second Detailed Annual Report of the Registrar-General for Ireland." Dublin: H.M. Stationery Office. 1906.

year was 4,391,565, as against 4,402,182 in the previous year, and an average of 4,481,504 for the ten years 1895-1904. In the course of the year the marriages registered in Ireland numbered 23,078; the births, 102,832; and the deaths, 75,071. The marriage-rate, which is 5.26 per 1,000 of the estimated population, shows an increase of 0.04 as compared with that for the year 1904, and is 0.20 above the average rate for the ten years 1895-1904, and the highest rate for any of these years; the birth-rate (23.4 per 1,000) shows a decrease of 0.2 as compared with that for the preceding year, but is 0.2 above the average rate for the ten years 1895-1904; and the death-rate (17.1 per 1,000) is 1.0 under the rate for the preceding year, and 0.9 under the average rate for the ten years 1895-1904. It appears, therefore, that the natural increase of population, or excess of births over deaths, was 27,761; the loss by emigration amounted to 30,676; a decrease of 2,915 in the population would thus appear to have taken place during the year.

There is not a complete record kept of the age of marriage, the law being satisfied by the entry of "minor" or of "full age" in the age column.

Of 23,078 men married during the year, 321, or 1.39 per cent., were minors; and of the women married 1,368, or 5.93 per cent., were under age. Of those married under age in 1905 the highest proportion of husbands (1.80 per cent.) and of wives (7.39 per cent.) was in the province of Ulster. It is observable that the percentage of persons married in Ireland who were under age is very far below the corresponding percentages in England and Scotland. These facts are, of course, in keeping with the observation that the marriage age is lower in an industrial than in an agricultural community. That a greater number of marriages take place in an industrial people is shown also by the fact that the marriages registered in proportion to population at all ages were most numerous in the province of Ulster, in which, however, the rate was only 5.7 per 1,000 of the population, according to the Census of 1901; Leinster comes next with 5.5 per 1,000; Munster third, with 4.7 per 1,000; and Connaught last, the rate being 4.1 per 1,000. The births registered during the year 1905 numbered 102,832—52,509 boys and 50,323 girls, or 104.3 of the former to every 100 of the latter—the rate afforded in proportion to the estimated population being 1 in 42.7, or 23.4 per 1,000, which is 0.2 above the average rate per 1,000 for the ten years 1895-1904. Of the 102,832 children whose births were registered in Ireland during the year 1905, 100,122, or 97.4 per cent. were legitimate, and 2,710, or 2.6 per cent., were illegitimate, being equal to the corresponding average percentages for the preceding 10 years. These results compare favourably with the returns for most other countries.

The deaths registered—75,071—were equal to a rate of 1 in 58, or 17.1 per 1,000 of the estimated population. The counties or county boroughs having the highest rates of mortality are Dublin County Borough, 23.1; Belfast, 20.4; Armagh County, 19.3; Wexford County, 18.5; and Tyrone County, 17.7.

Among the causes of death tuberculosis still holds first place, 11,882 persons having died during the year. Taking the mortality of the disease in relation to the mortality from all causes, it will be found that of every 100 deaths 16 were due to tuberculosis. The Registrar-General emphasises the fact that whereas in England and Scotland the death-rate from tuberculosis has gone down by nearly a half in the past forty years, in Ireland the rate now is higher than it was in 1864. Another point of contrast is noted. In England and Scotland the highest rate for tuberculosis is found in the population under five years of age; in Ireland it is found in the population between 25 and 35.

Curiously enough, the cause of the greatest number of deaths, after tuberculosis, is old age, which was responsible for 8,641. From heart diseases 8,170 died, and from bronchitis 7,462.

The year shows a further increase in the number of deaths from malignant disease. The aggregate was 3,291, in contrast to 3,055 in the previous year. Of the deaths in 1905, 1,443 were deaths of males, and 1,848 of females. The site of the disease was the stomach in 782 cases, the intestine in 183, the rectum in 180, the liver or gall bladder in 437, the uterus in 209, and the breast in 324.

The value of the report is increased by a series of instructive charts and diagrams.

NEW INVENTIONS.

WRIGHT'S COAL TAR INHALER.

On theoretical grounds the treatment of the inflamed mucous membrane of the air passages by medicated vapours commends itself to the physician. In practice, however, that particular method has not come into the general use that it apparently deserves. This neglect has doubtless been largely due to the lack of convenient and efficient apparatus for vaporisation. Messrs. Wright and Co., the well-known makers of coal-tar soap, have devised a simple plan for diffusing the vapours of coal-tar both for direct and for general inhalation. The apparatus is extremely simple, consisting of a metal receiver heated by an ordinary nursery night-light. Into the receiver is placed an absorbent block saturated with the coal-tar preparation, and any other drug, such as menthol, that it may be considered advisable to add. This inhaler is well worth an extended trial in bronchitis and other affections of the respiratory tract; but, above all things, in measles, influenza, and whooping cough, in each of which there is a definite source of local irritation in the shape of a specific pathogenic bacillus. The vapour given off from the inhaler may be inhaled directly, or may be diffused through the atmosphere surrounding the patient.

REVIEWS OF BOOKS.

TREATMENT OF CANCER. (*a*)

Dr. Shaw Mackenzie's views on the treatment of cancer, and the work he has done on the subject, are so well known that we need not do more than mention that his little book has now reached a fourth edition, a testimonial in itself to the amount of interest displayed by the profession. There is little that is new in this edition, and the whole subject is still in a tentative condition, so that the wise course is still to suspend judgment. Dr. Shaw Mackenzie's methods are, we believe, being extensively tried, and doubtless the experience of a few more years will decide how much of permanent value there is in them. In inoperable cancer no reasonably founded treatment is lightly to be rejected, or embraced.

LE SOL ET L'EAU. (*b*.)

This volume is the second fasciculus of the Traité d'Hygiene, which is being published monthly under the direction of MM. Brourardel and Mosny. In some respects this particular number forms a striking contrast to the works dealing with the subject at present in use. The different sections of the work are entrusted to men exceptionally well-informed on the portion for which they are responsible, and with one exception each department receives its fair consideration. The microscopical examination of the sediment is practically limited to the detection of intestinal worms, which the authors appear alone to regard as worthy of note.

The geological study of the soil by M. de Launay contains a warning against reliance on single analyses of water, which ought to be more widely appreciated in this country. He explains fully the influence of the soil in determining the character and potability

(*a*) "The Nature and Treatment of Cancer." By John A. Shaw-Mackenzie, M.D.Lond. Fourth edition, revised. London: Bailliere Tindall and Cox. 1906. 2s. 6d. net.

(*b*) *Le Sol et L'Eau.* By L. de Launay, Professor at l'Ecole de Mines; E. A. Martel, of the Comité Consultatif d'Hygiene; Ed. Bonjean Chef du Laboratoire du Comité Consultatif d'Hygiene de France; and J. Ogier, Chef du Laboratoire de Toxicologie de la Faculté de Medicine de Paris. Pp. 460. With two coloured plates and 80 illustrations. Paris and London: Bailliere, 1906. Price 10fr.

of the water. Two geological charts are fully explained, an example that is worthy of note, and which might be followed by English writers with advantage.

M. Bonjean deals with the physical, chemical and bacteriological action of the soil, and its bearing on the quality of the water. He gives especial attention to diseases of a reputed telluric origin.

M. Martel explains the circulation, emergence and contamination of subterranean waters, including a discussion on the use of flourescein as a means of identifying distant pollution, and the legal means for the protection of water supplies. The bacteriological, chemical, and microscopical methods of analysis are given in a compact form by MM. Ogier and Bonjean. The interpretation of results deservedly occupies a considerable space, as also does the article on water filters.

The D.P.H. candidate will turn with relief to this book. He will glean information either unknown or ignored by English writers; he should appreciate the romantic side of water supply, and will surely be grateful for the freshness of treatment of the subject. We know of no book on the subject so interesting, and its perusal will well repay all who can read the French language, and are interested in the bearing of water supply on public health.

DISEASES OF CHILDREN. (*a*)

IT used to be said, and we believe there are those who still maintain, that Great Britain is behind her civilised neighbours in her knowledge of, and practice in, diseases of children. The justification of this charge we are still seeking. True it is that the State has not realised its responsibility towards children in the same way that, for example, France and the Australian colonies have, but that British physicians and surgeons lag behind their *confrères* in skill in and acquaintance with, pediatrics we refuse to believe. The book before us is one written by a distinguished Austrian professor, which has had a wide sale in German-speaking countries, and it has now been translated and edited by an American physician of eminence. It may, then, not unfairly be taken as representing the last word of these countries—the ones that we are specially compared with to our detriment—on the subject with which it deals, and we can say without any disparagement to the book that while we cordially agree with its teaching as a whole, we are not conscious of having learned anything particularly new from it. The translation has been really well carried out, the book being done into good idiomatic English (or, dare we say, American?), while its value is distinctly enhanced by the editor's pithy notes. The work is arranged on the dictionary plan, diseases medical and surgical being treated of in alphabetical order. The descriptions are short and to the point, but so much has had to be inserted that there have necessarily been great sacrifices made in individual articles in the cause of brevity. Indeed, the qualified practitioner who wishes to know a little more than he is already familiar with will probably find the book unsatisfying, although for the student who is breaking new ground it is admirably adapted. He will find the article on congenital syphilis of great help, but the important subject of tuberculosis touched upon rather too lightly. Whatever may be the rule in Austria and America, we do not call cases of scarlet fever in which widespread gangrene of the oral and pharyngeal cavities developes "scarlatinal diphtheria" (page 414). We confine the latter term strictly to conditions associated with the Klebs-Löffler bacillus, and it is certainly the more convenient practice. The illustrations, as is the rule in Messrs. W. B. Saunders and Company's books, are clearly and well reproduced, but we are sorry to see in the appliances for infant feeding the objectionable artificial nipple attached to a long tube exhibited in one of the plates. The work is a handy and serviceable one, but it does not make us blush for British pediatrics.

(*a*) "Reference Handbook of the Diseases of Children." For Students and Physicians. By Prof. Dr. Ferdinand Frühwald, Chief of Clinic in the Vienna Polytechnic. Edited, with additions, by Thompson S. Westcott, M.D., Associate in Diseases of Children in the University of Pennsylvania. With 176 illustrations. Philadelphia and London: W. B. Saunders and Company. 1906.

ROYAL ARMY MEDICAL CORPS (*a*).

THIS guide is compiled with the object of assisting men of the Army Medical Service to make up their work for promotion examinations. Most of the subject matter is, therefore, to be found in the two Army publications with which they are expected to be familiar, namely, the Manual, and the Standing Orders of the Royal Army Medical Corps.

Part I., comprising half the text, consists of an exhaustive series of questions and answers on drill, discipline, etc., and is required for the first examination for non-commissioned officers. Instruments and appliances are suitably illustrated. Part II. deals with the additional subjects the knowledge of which is necessary for promotion to sergeant.

The Appendix (pp. 260—303) is a guide to the recently-promoted N.C.O., and contains instructions for routine clerical duties, and shows the method of filling up various official forms.

The Guide is sure to find favour with those for whom it is intended, except, perhaps, in the matter of price, as it is concise and comprehensive.

KIRKBY'S PRESCRIBING (*b*)

THIS is the second edition of a little work, the first of which was well-received. In these days, when prescription-making is gradually being lost sight of, it is refreshing to meet with books such as this which tend to prevent its complete disappearance from the medical curriculum. Students are grossly ignorant regarding this very important subject, mainly because it is badly taught or very often not taught at all in many of our medical schools. The little book before us gives a very thorough account of its subject. Incompatibilities, solubilities, and the various pharmaceutical preparations are very comprehensively described and explained. Under each pharmacopœial remedy a list of its more important incompatibilities is given. Some of the substances used in medicine are given in a list by themselves, and under each is placed a reference to the impurities which they may contain. A number of exercises in practical dispensing and in the testing of drugs have been added, and the student who can carry out these satisfactorily will have no difficulty in performing this part of his duties in actual practice. This edition has been enlarged and extended, but otherwise the book remains the same as before. We wish it were used in every medical school throughout the country by students before presenting themselves for their final examination. We congratulate the author on his efforts to raise the standard of prescribing and dispensing amongst medical students; and trust this edition will meet with even greater success than the last.

CLIMATIC TREATMENT. (*c*)

DR. HUGGARD, in his "Climatic Treatment," has set himself a bold task, namely, "to place the therapeutics of climate on a secure foundation," which seems to us about as ambitious as trying to place religion or philosophy on a secure foundation, and as hopeless. Still, it is well to have ideals, and Dr. Huggard's ideal not only is a noble one, but he has

(*a*) "Guide to Promotion for Non-Commissioned Officers and Men of the Royal Army Medical Corps, with Appendix on Hints for young N.C.O.s." By Capt. S. T. Beggs, M.B., Royal Army Medical Corps (M), formerly House Surgeon and House Physician, Royal Victoria Hospital, and Demonstrator of Physiology, Queen's College, Belfast; Examiner and Lecturer, St. John's Ambulance Association, &c., &c. 1906. London: Gale and Polden, Ltd. Pp. 303. Price 3s. 6d. net.

(*b*) "Practical Prescribing and Dispensing for Medical Students." By William Kirkby, sometime Lecturer in Pharmcognoscy in the Owens College Manchester, Second edition. Manchester: Sherratt and Hughes.

(*c*) "A Handbook of Climatic Treatment, including Balneology." By William R. Huggard, M.A., M.D., F.R.C.P., H.B.M. Consul at Davos, Switzerland. London: Macmillan and Co., Ltd. 1906. 12s. 6d. net.

succeeded in writing the best and most useful book we know on climatology and balneology. But we should be sorry to say that the therapeutics of climate are thereby safely secured to our children's children. Indeed, it is probable that people would rather resent being told that their favourite spot was not good for rheumatism because of its high relative humidity, when they have been there over and over again, and been cured of their rheumatism. And it is quite impossible, as every practitioner knows, to get people to "believe" in a place that they do not like. The fact is, that the social and human environment is as large a factor in almost any "cure" as the amount of calcium carbonate in the water or the proportion of sunny days in the year. We have no doubt that the analysis of the waters of Abana and Pharphar would have been found to differ but slightly from that of Jordan; in fact, the quantity of albuminoid ammonia in the latter was probably disquietingly high; but the Jordan cured and Abana and Pharpar did not. Which is another way of saying that the element of charm in a place is a great factor in the cure of the patient, as is the element of confidence in the physician, or any other obligatory condition. Charm defies analysis, and is as likely to do so as long as one lady finds that Falmouth in the winter braces her up, and another that the mistral is the most helpful factor on the Riviera for the restoration of health. But we are far from saying that the scientific study of climatology is not desirable; it is eminently so, and Dr. Huggard's book before us is one of the few works in the language which preserves a sane and judicial outlook over the competing claims of spas and watering-places. Moreover, the knowledge of the author is sufficient to enable him to systematise and lay down general principles, and he may confidently be looked to for wise and tolerant advice as to the most promising line to be followed in treatment. Among all the information the author has collected, it is hardly surprising that minor errors should have entered, but these are neither numerous nor serious. For instance, though it may concern the residents at Hastings and St. Leonard's to know that those towns "belong to the more bracing class of seaside resort," it will not do them much harm, and in the same way, though the inhabitants of Eastbourne might be surprised to hear that their western and south-western downs protect them from the north winds, they would probably only wish they did. But it is well to mark clearly that Dr. Huggard's is not of the ordinary type of climate book—half guide-book and half pseudo-scientific froth—but a praiseworthy diligent, serious study of climatology and balneology by a discriminating physician.

DISEASES OF NOSE AND THROAT. (a)

IF Mr. Parker has waited a good many years before rushing into the thorny paths of systematic authorship, his text-book, now that it has appeared, is considerably the gainer. To write a good systematic treatise even on a special department of surgery needs a life-time of experience and reflection if it is not to be either a re-hash of other people's opinions or a precocious and unsatisfying product of premature ambition. Now Mr. Parker's book is neither of these, but a thoughtfully planned and very carefully written treatise on the diseases of the nose and throat which we unhesitatingly commend to all students and practitioners as a particularly clear and temperate guide. It is not daringly original, nor, on the other hand, pompously platitudinous; but it sails a judicious course between the Scylla and Charybdis which threaten the author of a text-book. As already mentioned, it's chief characteristic is extreme care, the views of others being conscientiously set forth, and the author's own opinions clearly and concisely stated. Mr. Parker has a happy knack of directness of description which enables him, without beating about the bush, to indicate in a few appropriate words all that is needed for a person of ordinary intelligence to grasp exactly what is intended. And this is the quality of all others that goes to the making of a popular and useful text-book. We notice certain minor omissions such, for instance, as the absence of mention of eucaine lactate. The objection that Mr. Parker makes to the use of eucaine, namely, its insolubility, is, of course, not valid now that this salt has been introduced, and we venture to think that eucaine lactate and adrenalin will eventually render the use of cocaine as a routine anæsthetic superfluous. The description of tracheotomy might well have been expanded, for though all the thirteen (or is it thirty?) possible complications need not have been reproduced, in a special treatise one would have expected ampler details than are actually given. The case for and against intubation is fairly stated, and we agree with the author as to the general superiority of tracheotomy for the reasons he gives. We suspect, however, that the author is not fully *au fait* with the practice of intubation, or he would have mentioned the satisfactory method of extraction of the tube by expression, and he would not have omitted the essential detail of tying the child's hands down if a ligature be left strapped to the cheek. The odd statement is made (page 86) that the "complication" of the upper respiratory tract in the acute specific fevers "has no special features peculiar to the fever which causes it." We must in fairness to the author, as judged from the rest of the book, conclude that his pen played him some scurvy trick when he wrote those words. Mr. Parker rightly says that it is somewhat anomalous that the acute infectious diseases should be included in a book of this type, and it is on this excuse that we forgive the statement that Koplick's spots are "frequently" absent in measles, and that the very infectious and highly important involvement of the nasopharynx in scarlet fever is so cavalierly glossed over. The description of adenoid growths and their consequences is particularly good, especially the sections dealing with nasal and palatal deformities. Sinus suppuration is also fully described, and we note that puncture through the canine fossa has given way in the author's opinion to opening through the inferior meatus. This is the general view now; most surgeons seemingly have come round to it. We are glad to see the method of opening a quinsy by thrusting sinus forceps through the soft palate—the only satisfactory way of tapping the abscess—is well described and insisted on. A word must be given to the illustrations. They are very clear and helpful, and though many are old and few are original, they are all well chosen. The paper and get-up of the book are on a par with the high character and judicious teaching of its contents.

(a) "A Guide to the Diseases of the Nose and Throat, and their Treatment." By Charles A. Parker, F.R.C.S.Edin., Surgeon to the Throat Hospital, Golden Square, W. With 255 illustrations. London: Edwin Arnold. 1906. Price 18s. net.

THE DISEASES OF WOMEN. (a)

WHEN a work reaches its fifth edition it is generally supposed to have proved its use and value in the literature of the special subject it treats of. We have perused the pages of this book with very great pleasure. It is written clearly and simply, so that its meaning can be easily understood. It comprises nearly all that is known or can be described concerning the diseases peculiar to women and gynæcological operations. The work is divided into 57 chapters, running over some 523 pages, with a copious index. The printing is good and the volume handy and not bulky. In this edition much new matter has been introduced in relation to chorion, epithelioma, extra-uterine gestation, and tumours of the ovary, including an entirely new section on metastatic cancer of this organ.

(a) "The Diseases of Women." A Handbook for Students and Practitioners. By J. Bland Sutton, F.R.C.S.Eng., Surgeon to the Middlesex Hospital, and Senior Surgeon to the Chelsea Hospital for Women, and Arthur E. Giles, M.D., B.Sc.Lond., F.R.C.S.Edin., Surgeon to the Chelsea Hospital for Women, and Gynæcologist to the Tottenham Hospital. Fifth Edition, with 129 illustrations. Pp. 536. Messrs. Rebman, Limited, London and New York. Price 11s. net. 1906.

MEDICAL NEWS IN BRIEF.

Joint Hospitals Conference of Great Britain and Ireland.

AN important conference of representatives of hospitals in Great Britain and Ireland, of those interested in hospital administration, and of medical men, was held on Dec. 6th in the Botanical Lecture Theatre, University College, to consider the question of hospital reform. A set of proposals drawn up by a joint committee of the British Medical Association and of non-medical representatives of boards of management of hospitals, had already been sent out to various institutions throughout the country, upon which it was considered that reform could best be carried out. One hundred and forty-nine institutions expressed their intention of sending delegates, and twenty-nine announced that they intended to take no action.

Sir William Church, who presided, said that the hospital system as at present administered was greatly in need of reform. Especially was it so with regard to out-patients. The whole question had become more difficult because of its extreme complexity. They had hospitals on every hand appealing to the public in every way for increased funds to meet their needs. They not only asked for funds to meet their existing needs, but for carrying out extensions of the work they were engaged upon. Although it was nothing to do with the subject, he had to say that many hospital advertisements were anything but dignified. What he thought they really needed was co-operation between hospitals, and not competition.

Sir Henry Burdett moved a resolution calling upon the meeting to approve of the principles drawn up and circulated. He thought that an effectual remedy must be applied to the existing evils attaching to free medical relief by hospitals. Medical practitioners were injured by the abuses and misuses of the present system of free medical relief. One great evil was that people of the poorer classes went to hospitals for treatment for trivial ailments which those who had to pay for their doctors would take no notice of. The poor had an idea that disease came from providence, and could only be cured by drugs. That was an idea which ought to be got rid of. Cleanliness and proper feeding were often what were required. Drink had much to do with the question, and the gin palace at one corner of a street and a free dispensary at the other formed one of the enormous anomalies which existed at the present day.

Dr. F. M. Pope, F.R.C.P., who seconded, said that the unchecked distribution of free medical relief had taken away the doctors' patients, and had created an idea that medical attention was a thing not to be paid for, or, if at all, in a very inadequate manner.

Several members did not care to express agreement with the general principles laid down.

The original resolution stood as follows:—"That this Conference of representatives and supporters of hospitals, medical practitioners, and others interested in hospital administratjon in Great Britain and Ireland, approves generally of the principles contained in the proposals drawn up by the Joint Hospitals Committee and circulated to Hospitals in August, 1906." As amended and passed it affirmed that the Conference welcomed the further discussion of the principles laid down.

Dr. G. A. Heron gave it as his opinion that the out-patient evil would be greatly lessened if hospitals would refuse to treat cases where no good could possibly be done.

The amended resolution was carried. A committee was appointed, to act in conjunction with the Hospitals Committee of the British Medical Association, to yet further discuss and consider the proposals for hospital reform. It was proposed to make the Conference an annual affair.

Charing Cross Medical School.

THE distribution of prizes to the students of the Charing Cross Hospital Medical School took place on the 5th inst., Dr. Amand Routh presiding. The Dean (Dr. Christopher Addison) in his report stated that the excellent results obtained by the students in their various examinations had been fully maintained during the past year. Out of some 200 entries there had been an average pass of over 72 per cent. Sir Arthur Rucker then handed the prizes to the successful students, among whom the Governors' Clinical Gold Medal was awarded to W. K. Beaman, the Llewellyn Prize to W. S. Fenwick, the Golding Prize to S. S. Parkinson, the Pereira Prize to W. S. Fenwick and J. W. Heekes (equal), and the Huxley Medal to L. M. Webber, scholarships being gained by B. F. Eminson, N. C. Lake, H. Smith, F. S. Poole, and D. A. Powell. The Principal of the University of London subsequently delivered a short address, in the course of which he congratulated the students on entering a profession which would not only enable them to achieve personal success but to become benefactors of mankind through the alleviation of suffering. The proceedings concluded with a vote of thanks to Sir Arthur Rücker, proposed by Lord Kilmorey, Chairman of the Hospital.

Birmingham Red Cross Society.

To organise a local branch of the British Red Cross Society, a meeting was held at the Birmingham University on December 5th, under the chairmanship of Professor Gilbert Barling. The object of the society is to supply voluntary aid to the sick and wounded during the time of warfare, and during the time of peace to ascertain how the necessary supplies may be obtained when the need shall arise for them. Apologies for non-attendance were read from the Marquis of Hertford, Sir Oliver Lodge, Mr. Neville Chamberlain, and Mrs. Joseph Chamberlain. The Chairman said that hitherto the work of the society had been small and imperfect owing to improper organisation. Although we were in no anxiety to be involved in warfare at the present time, we did not know when we might become involved in some important struggle, and it was necessary to form such an organisation, which would assist in securing aid for the sick. Mr. Antony A. Bowlby, C.M.G., F.R.C.S., surgeon to St. Bartholomew's Hospital, London, then addressed the meeting on Red Cross work. He said that this was the first meeting of the society that had been held out of London. On the proposition of Lieutenant-General Phelps it was decided that a branch of the British Red Cross Society be established. A committee of local ladies and gentlemen was formed, and the Marquis of Hertford was elected as president of the branch.

New Accident Hospital for Barry.

Mr. J. Spencer Low conducted a Local Government Board inquiry at Barry Dock on December 4th into an application by the Barry District Council for sanction to borrow £7,115 for a new town accident hospital at the junction of Tynewydd Road and Wyndham Street, Barry Dock. The Clerk said that there was great need for a suitable accident hospital at Barry. The present premises were not only inadequate and unsuitable, but defective from a hygienic point of view. The Commissioner asked how the medical men were appointed on the staff of the hospital, and was told that the Council appointed them. A rota for the year was drawn up, but not half the medical men of the town are on the staff now. The Inspector: So it is a life appointment?—Yes. (Laughter.) Does anyone cease to become a member of the staff?—Yes. Through death or any other causes?—Yes.

Alleged Illegal Operation at Bristol.

AT the Coroner's Court, Merchant Street, on the 5th, the City Coroner held an inquiry into the cause of the death of Kate Radford, a married woman, æt. 28, upon whom it is alleged an illegal operation was performed by a woman named Florence Cowle. The latter was arrested on November 25th at her home in City Road, and on the following day brought up at the Bristol Police Court on the above charge and remanded. The proceedings were watched on behalf of the police by Deputy Chief Constable Croker and Mr. F. P. Tyrell (from the Town Clerk's office), and Mr. F. E. Metcalfe for Mrs. Cowle (accused), who was present at the hearing.

VERDICT OF MURDER.

The jury announced the following decision:—"We unanimously agree with the medical evidence, that the death of Mrs. Radford was due to peritonitis and blood-poisoning, which we consider was brought on by a miscarriage caused by an illegal operation performed by Mrs. Cowle."—The Coroner: That is a verdict of murder?—The Foreman: Yes, sir.

Strike of Medical Students in Calcutta.

THE great bulk of the Bengali students in the Campbell Medical School, Calcutta, numbering about 160, went out on strike at the end of October. The alleged "grievances" leading to this action were of so flimsy a character that there can be little doubt that the young men have been acting under the inspiration of political agitators. A large hospital is attached to the school, and apparently it was thought that the patients would suffer from the absence of the students, but this has not been the case, owing to the existence of a large supernumerary staff and to the devoted labours of nurses, teachers, and others. The strikers seem to have anticipated that they could secure admission to the other medical colleges of the city, but they were refused at the Calcutta Medical School and at the College of Physicians and Surgeons. The few students who remained at the school have been subjected to great pressure to join the strikers, and some of them have been in such bodily fear that they have not ventured away from the hospital grounds. After the strike had lasted nearly a fortnight, Major J. C. Vaughan, I.M.S., the superintendent, issued a notification to the effect that, the time fixed for return to work having expired, he had decided, with the approval of Government, to close further negotiations with the students. He had already dismissed from the school thirteen ringleaders of the strike, and he had now to intimate that all those who had not resumed work by that date were held by their own act to have severed their connection with the school, and to have ceased to be students of the school. But as many who had absented themselves from their work had been induced to do so by evil outside influences, he did not wish to close the door entirely against them. Therefore students desiring re-admission must make application, and each case would be considered on its merits. No one would be admitted during the current year unless the circumstances seemed to warrant the exercise of clemency on his behalf, and unless there was reasonable chance of his completing the studies apportioned for the year.—*The Times.*

Medical Sickness and Accident Society.

The usual monthly meeting of the Executive Committee of the Medical Sickness, Annuity and Life Assurance Society, was held in London on 30th ult. There were present: Dr. de Havilland-Hall, in the chair, Drs. J. Brindley James, Frederick S. Palmer, J. W. Hunt, St. Clair B. Shadwell, F. J. Allan, M. G. Biggs, W. Knowsley Sibley, Walter Smith, M. Greenwood, J. B. Ball and Mr. J. F. Colyer. The record of the business is still good and since the beginning of the year a considerable addition has been made to the cash reserves. The sick claims have so far been moderate, but there are signs of an influenza epidemic, and if this becomes at all general it is certain to make its mark in this claim account of the Medical Sickness and Accident Society. The reserves which the Society now possesses have been made to cover risks of this description, and are ample for all purposes. Prospectuses and all particulars on application to Mr. F. Addiscott, Secretary, Medical Sickness and Accident Society, 33, Chancery Lane, London.

St. Thomas's Hospital, London

THE following have been selected as House Officers: Casualty Officers (from Jan. 1st, 1907).—(Senior) A. W. Hooker, M.B., B.S.Lond., M.R.C.S., L.R.C.P.; (Junior) J. H. Drew, M.B., B.S.Lond., M.R.C.S., L.R.C.P. Resident House Physicians.—H. C. Squires, M.A., M.B., B.Ch.Oxon., M.R.C.S., L.R.C.P.; A. N. Dickson, M.R.C.S., L.R.C.P.; M. A. Cassidy, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; W. O. Sankey, M.B., B.S.Lond., M.R.C.S., L.R.C.P. House Physicians to Out-Patients.—E. V. Dunkeley, M.B., B.S. Lond.; H. A. Nightingale, M.R.C.S., L.R.C.P. Electrical Dept. and X-Ray Dept.—H. A. Kisch, M.B., B.S.Lond., M.R.C.S., L.R.C.P.

University of London.

The following candidates have passed the M.B., B.S. Examination, with honours:—E. F. Finch (*b*), Univ. of Sheffield; R. A. Hendry (*b*, *e*), Uni. of Liverpool; C. A. Pannett (*B.Œc.*), St. Mary's Hosp. A. Pearson (*a*), Guy's Hosp.; G. F. Stebbing (*d*), Guy's Hosp.; D. C. Taylor (*d*), Univ. Coll.; W. H. Trethowan (*a*), Guy's Hosp.; E. Wragg (*b*), Guy's Hosp.

The following have also passed M.B., B.S. Examination:—W. Arnott, T. H. Barton, H. H. Bashford, A. W. Berry, J. S. Bookless, A. H. Bradley, Hilda M. Byles, H. J. Cates, I. R. Cook, I. J. Davies, C. H. Davis, S. W. Daw, J. B. Dawson, A. B. Edwards, W. H. A. Elliott, E. W. Gieson, L. F. Hurst, B. W. Jones. Edith A. Jones, H. A. Kisch, W. A. McEnery, P. F McEvedy, I. C. Maclean, A. T. Marshall, Dorothea C. Maude, C. A. L. Mayer, Sylvia May Moore, E. H. A. Pask, Eleanor W. Perkins, W. C. Pickering, A. Randle, E. F. Reeve, J. E. Robinson, W. O. Sankey, H. B. Scargill, W. L. Scott, Zilla Mary Scruby, J. E. Smith, Grace Maud Stagg, G. W. Sudlow, Bessie W. Symington, A. K. R. W. Taylor, Ida Clare Tengely, S. Upton, Margaret I. Waller, E. J. Wyler, G. P. Young, A. Zorab.

(*a*) Distinguished in Medicine.
(*b*) Distinguished in Pathology.
(*d*) Distinguished in Surgery.
(*e*) Distinguished in Midwifery and Diseases of Women.

University of Dublin—Chair of Surgery.

THE Board of Trinity College have appointed Edward Henry Taylor, M.D., to the Professorship of Surgery, vacated by Edward H. Bennett, M.D. Dr. Taylor has been acting as deputy for the Professor of Surgery since October, 1904.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT SURGICAL LITERATURE.

The Surgery of the Lung, with an Illustrative Case.—Fink (*Indian Med. Gazette*, November, 1906) discusses the symptoms and his treatment of a patient who was stabbed in the chest. A red mass, about the size of a man's hand, was found protruding between the ninth and tenth ribs, through a wound about three inches long in the mid-axillary line. On three or four occasions before admission to hospital a hissing sound had been heard during respiration. The protruding mass consisted of collapsed lung and pleura. Costal and visceral pleura were both torn. The parietal wound was firmly plugged by the protruding lung, which did not crepitate. Breathing was fairly quiet, but the patient complained of pain in the shoulder and upper part of the chest. On stretching the wound slightly with the finger air entered the pleural cavity with a hiss, and the patient complained of some pain. There was little hæmorrhage. The patient refused operation on the night of admission, and slept a few hours. Next morning the whole protruding mass of lung was ligatured by interrupted silk ligatures, and excised with a sharp scissors. The ligatured portion was returned into the pleural cavity. This procedure was accompanied by a slight rush of air, but did not cause the patient much discomfort. The whole operation was performed without an anæsthetic. The subsequent history was uneventful, the patient making an excellent recovery. The lung became normal to percussion and auscultation. The author draws attention to the following facts:—Though air had undoubtedly entered the pleural cavity, the patient had no dyspnœa. With such a large opening in the thoracic wall, one would have expected serious collapse of the lung; but such did not occur. On the contrary, a piece of the lung was pushed out of the thorax. The parietal wound became plugged, and thus more external air was prevented from entering the pleural cavity. The wounded part of the lung being outside the thorax, no air escaped from the lung into the pleural cavity. There were probably some adhesions between the parietal and viceral pleura at the time of the operation. The ligature applied to the protruding mass of lung bound the two pleural surfaces more securely together, and in this way the collapse of the lung was effectively prevented. S.

The Operative Treatment of Ulcer of the Stomach and its Chief Complications.—Mayo Robson (*Brit. Med. Journ.*, November 17th, 1906) states that on ample evidence we may accept the fact that at least one-third of all the cases of ulcer of the stomach treated medically ultimately succumb to the disease, or to one of its many complications, and that one-half or two-thirds of the cases that recover relapse. In the author's own experience alone in over 400 operations of various kinds the total mortality has been only a little over 3 per cent., and the patients completely relieved have been over 90 per cent. Ulcers may be classified into acute and chronic. In acute ulcer the treatment should at first be medical, and, above all things, it should be thorough. If after three months' careful feeding, at first on milk only, the patient is not free from digestive troubles, the question of surgical treatment should be seriously considered. In chronic or relapsing ulcers, if medical treatment has had a fair trial, yet non-relief or relapse after temporary freedom from symptoms occurs, surgical treatment ought to be urged. Surgical treatment may be direct, as in the excision of the ulcer, or indirect as gastro-enterostomy, pyloroplasty, etc. The author's experience of direct operations alone are unsatisfactory. The operation of excision of the ulcer-bearing area with the performance of an independent gastro-enterostomy will probably in the future be more frequently performed, especially as 59 per cent. of cases of cancer of the stomach give a history of chronic ulcer. Mayo Robson considers pyloroplasty and its modifications an unsatisfactory treatment compared with posterior gastro-jejunostomy. The ill effects, as regurgitant vomiting, said to follow the latter operation can probably all be avoided by correct technique. Death from asthenia is no longer a danger, as feeding can be begun immediately after operation. The danger of primary hæmorrhage is entirely avoided by continuous sutures embracing the margins of the openings between the two viscera. The only complication that perhaps is unavoidable is extremely rare, *i.e.*, peptic ulcer of the jejunum. The author thinks the condition will in future be avoided by making the opening sufficiently large, so that there can be no possibility of stasis. Also, by careful dieting, so as to thoroughly cure the hyperchlorhydria. The author's experience in perforation is that excision of the ulcer is not necessary to success, and that a folding-in of the edges of the rupture, with a careful application of a serous suture, and, if possible, an omental graft laid over it, gives the best results. Gastro-enterostomy performed at the same time, if the patient can stand the strain, has the following points decidedly in its favour:—(1) Other ulcers present at the time will probably be cured. (2) If a second ulcer is on the point of perforation, this will probably be prevented, as the tension and pressure on the stomach walls will be avoided. (3) More secure healing of the sutured ulcer is likely to occur. (4) The risk of hæmatemesis is diminished. (5) Saline aperients may be given early, and so secure more efficient drainage of the peritoneal cavity. (6) Earlier feeding is possible. Regarding hæmorrhage, general treatment is successful in arresting acute hæmatemesis in from 93 to 97 per cent. of all cases, therefore medical treatment should always have a fair trial in every case. Surgical treatment is direct and indirect. Mayo Robson is of opinion that the indirect method of posterior gastro-jejunostomy is usually an efficient means of treating this condition, and it is only under exceptional circumstances necessary to treat the ulcer directly, thus avoiding a possibly prolonged search for the bleeding vessel. In pyloric stenosis and obstructive dilatation it is generally agreed that gastro-jejunostomy is the procedure that should be followed, not only because it can be done with little risk, but also because the after results in these cases are extremely satisfactory. The treatment of gastric tetany is essentially surgical. Drainage of the stomach by gastro-enterostomy relieves the tetany, and at the same time cures the disease producing it, as in almost all cases there is a grave mechanical obstruction to the onward passage of the food. In hour-glass stomach it seems quite clear, according to statistics, that whether gastroplasty or gastrostomy be adopted for making a communication between the two stomach cavities, a gastro-enterostomy ought to form part of the operation in order that the ulceration giving rise to the disease may be cured. S.

The Modern Treatment of Intracapsular Fractures.—Hunt (*Medical Record*, November 3rd, 1906) reports three cases in which he used Maxwell's treatment. This comprises the old downward extension with adhesive straps, with side traction at the groin carrying a pull upwards, outwards, and forwards. This takes up the weight of the thigh, holds it opposite the point of fracture, and draws the capsule like a tight sleeve over the fragments, holding them in place. In Case I. the patient, a woman, was over 80 years old. Beside the fracture the patient had a troublesome cough, and commencing bed sores. She had a long and tedious illness, but in a few months made a good recovery,

and was about in four months. The leg is somewhat shorter than its fellow, but the patient walked without a limp, and is alive and well to-day. Case II. was a woman of 75. She had no trained nurse, and on account of living some way out of town, was seldom seen. Patient recovered without any limp, and with about an inch or less of shortening. Case III. was a woman 82 years of age. Maxwell's treatment was carried out for forty days, when the patient was allowed up. Some ankylosis of the knee-joint occurred, but subsequently disappeared, and the patient was able to get about without any limp, so that no one would suspect that she had injured her hip. S.

Congenital Distichiasis.—A. R. Brailey (*Trans. Opthal. Soc.*, 1906) reports a case of this rare condition, and summarises the cases already reported, as well as four unpublished cases. The case occurred in a healthy boy, æt. 14, who was suffering from what appeared to be ordinary chronic conjunctivitis, but on close examination it was found that this was due to the presence of many fine hairs which, arising from the posterior margin of the upper and lower lids, lay directly on the cornea. The lids and the natural cilia were quite normal. The accessory cilia formed a single closely-placed row of fine, delicate, almost colourless hairs half the length of the normal cilia, from which they were separated by the whole width of the inter-marginal space. These abnormal cilia seemed to grow from the meibomian glands, but on pathological examination it was found that the meibomian glands were quite absent, and their place taken by the follicles of the erring cilia. The only departure from the normal in the patient was the presence of two accessory bicuspid teeth in the right lower jaw. Kuhnt defines distichiasis as "a congenital condition in which the meibomian glands are absent, and their place taken by a row of accessory cilia with all their attributes." This definition is supported by the histological examination of Brailey's case. Brailey thinks the term distichiasis should be confined to this condition, and not applied to those cases which are really grades of trichiasis due to trachoma and allied disorders of the lids. He differentiates the conditions thus:—Distichiasis occurs in lids otherwise normal with the exception of absence of meibomian glands, whilst in trichiasis the whole lid is distorted, the new hairs spring up anywhere along the lid margin, and the sharp posterior margin of the lid is lost. Distichiasis is noticed in childhood, or about puberty—an age when trichiasis is seldom seen. M.

Tubercle of the Bulbar Conjunctiva.—W. I. Hancock (*Trans. Opthal. Soc.*, 1906) reports a case in a child, æt. 12. Two months before seen the patient was struck in the eye by a skipping rope. A fortnight later a small red patch was noticed which had grown rapidly. Beneath the corneal limbus was found a round, pinkish-red, firm nodule, with rough surface studded with fine yellow points. It measured 8 mm. and was adherent to the episclera, with much engorgement of the neighbouring conjunctival vessels. Right pre-auricular gland was enlarged, also right and left sub-maxillary glands to a slighter extent. No evidence of tubercle in the boy. The growth was removed by excision and scraping. It had penetrated the sclera, and the ciliary body was exposed, but by covering the wound by a large conjuctiva flap healing took place by first intention. Two months later the wound was soundly healed and free from redness, and vision, etc., were quite normal. The growth was typically tubercular, the tubercle bacillus being found in small numbers. M.

The Surgery of the Upper Abdomen.—In this article J. Boucher (*New York Med. Journal*, November 10) deals with gall stones, duodenal and gastric ulcers, the methods of diagnosis, and the appropriate treatment in each class of case. In gastric ulcer he discusses the important question, Which cases are medical and which cases are surgical? The dividing line cannot be drawn for some years to come. Many patients with the first attack without serious hæmorrhage, who can give up time, and who realise the importance of prolonged rest, will recover under medical treatment. The author thinks that the following types should be considered surgical:—1, Cases of relapsing acute hæmorrhage; 2, cases with persistent hæmorrhage, causing anæmia; 3, perforations; 4, recurrent ulcer, pure and simple, attended with dyspepsia and starvation; 5, pyloric obstruction; 6, adhesions following ulcer or independent of it; 7, scar contraction of the body of the stomach, giving hour-glass condition; 8, some cases of intractable dyspepsia originating in an ulcer, and for which the definite pathology is unknown.

The Preventive and Abortive Treatment of Mastoiditis.—W. Bryant (*Post Graduate*, November) writes this paper with the object of proving that prophylactic treatment is successful in preventing mastoiditis, and that abortive treatment, if commenced before the inflammation is far advanced, will, as a rule, obviate the necessity for a radical mastoid operation; he summarises his paper in the following way:—1. Orthopædics of the nose occupy a basic and important position in regard to prevention of mastoid inflammation. 2. Localised occlusion of the nasopharyngeal tract, and interference with the normal air currents of the head, are important predisposing causes of mastoiditis, and prophylaxis demands their correction. 3. Disturbance of the mucous membrane of the nasopharyngeal tract predisposes to mastoiditis and requires treatment. 4. Prophylaxis of mastoiditis in cases of chronic middle ear suppuration is accomplished by cure of the suppuration, which can be done before the involvement of the bone is extensive. 5. Abortive treatment will succeed in the vast majority of acute cases if commenced early. 6. Care of the middle ear inflammation, and Wilde's incision are the most important abortive procedures in mastoiditis. G.

The Prevention of Epididymitis.—W. Belfield writes (*New York Med. Journal*, November 24) an account of a method he has tried with success in four cases of gonorrhœal infection of the posterior urethra, in which the symptoms pointed to spread of infection along the vas deferens. The vas is exposed by a small incision half way up the scrotum, and fixed to the skin by a silkworm suture, which passes through the lumen of the duct. Each day a blunt hypodermic needle is passed into the canal, and an antiseptic solution syringed up into the ampulla and seminal vesicle. The author claims the following advantages for this method of treatment. The patient is saved from an attack of epididymitis, and the great danger of sterility which follows such an attack. If occlusion did by any chance occur, it would be in the vas, and could there be effectively dealt with by a plastic operation later on. It saves the patient much time, as the treatment does not require the patient staying in bed. The operation is done under local anæsthesia, and at its conclusion the patient can walk away to his business. G.

Fracture of the Anterior Superior Spine of the Ilium by Muscular Action.—Bebee reports a case (*New York Med. Journal*, November 17) in a boy of nineteen, who was running in a race, suddenly heard a snap, and felt a sharp pain in his right hip; it did not stop him from finishing the race. The anterior superior spine of the ilium on the right side was blunt, vague in outline, and tender to pressure, while the spine on the left side was sharp and prominent. Beneath the skin on the right side was a hard mass about an inch below the right spine. This mass moved freely, and produced no crepitus; a radiograph showed that a triangular piece of bone had been detached from the ilium. No bandages or treatment were used. In six weeks the patient could use his right leg as well as his left, the limp which followed the injury only lasting for about three weeks. Only four other cases of this kind have been recorded. Several cases have occurred of tearing off of the anterior inferior spine by the action of the rectus muscle. In the five cases in which the anterior superior spine has been detached all have occurred in boys of 17 or 19 years, and all have happened while the patient was running. It seems probable that the condition is really a separation of the epiphysis by the contraction of the sartorious muscle. Beyond rest in bed for a short time, the cases require no further treatment. G.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions, the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

PROVINCIAL.—You are, in our opinion, quite justified in taking the stand you propose with regard to Christmas festivities at your hospital. It is natural that nurses and convalescent patients should wish to have a "good time" at Christmas, but entertainments can be given in the board room or similar place, which are far more suitable for festivities than the wards, where there may be sick and even dying patients. No doubt there may be some hardship in individual cases, but careful management can generally secure every patient fit for enjoyment having some share in festivities, without hurting the feelings of relatives of the seriously ill ones.

HAYWARD'S HEATH.—There is a County Nursing Association, of which Miss Dyer is superintendent. It was founded some three or four years ago, and now covers 82 parishes and employs about 50 nurses.

THE BRITISH PHARMACOPŒIA.

F.R.C.P.—The report of the Committee of Reference in Pharmacy has just been presented to the Pharmacopœia Committee of the General Medical Council, and published. It contains recommendations with respect to many published criticisms of the 1898 B.P. You can obtain it from Spottiswoode and Co., Ltd., 54 Gracechurch Street, E.C. It will be found to contain over 300 recommendations for alteration in the preparation and assaying of drugs, all the result of a practical acquaintance with them, which pharmacists have better opportunity of obtaining than medical men.

AGNES.—We were very sorry to hear of the death of Sister Eliza, whose personality and work were well known to us. We are glad of the particulars you send us, but we have not space for such an article as you propose.

ANÆSTHETIC (Stafford).—We cannot say it accords with our experience that vomiting is more severe after ether than after chloroform. On the contrary, our inclination is to the opposite view. Different men's experiences differ, but we are not inclined to give way on the point.

D. S. (Clacton).—Thanks for your letter and for the information it contains. Please see comments in editorial columns.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 12th.

HUNTERIAN SOCIETY (London Institution, Finsbury Circus, E.C.).—8.30 p.m.: Discussion on Toxæmic Insanity (opened by Dr. K. Will, Dr. W. Rawes, and Dr. B. Pierce).

DERMATOLOGICAL SOCIETY OF LONDON (11 Chandos Street, Cavendish Square, W.).—5.15 p.m.: Meeting.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—5 p.m. Bradshaw Lecture:—Mr. E. Owen: Cancer, its Treatment by Modern Methods.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. L. Cheatle: Clinique. (Surgical.) 5.15 p.m.: Lecture:—Mr. A. H. Tubby: Surgical Diseases of Children.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—5 p.m.: Demonstration:—Dr. D. Grant: Case Taking.

THURSDAY, DECEMBER 13th.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY (20 Hanover Square, W.).—5.15 a.m.: Adjourned General Meeting. 5.30 p.m.: Paper:—Dr. L. Williams: The Treatment of Gout by the Ingestion of Common-salt-containing Waters.

BRITISH GYNÆCOLOGICAL SOCIETY (20 Hanover Square, W.).—8 p.m.: Specimens will be shown by Dr. Aarons, Mr. J. F. Jordan, Dr. Swanton, and Mr. C. Ryall. Papers:—Dr. Hodgson: Cause of Fatal Collapse after Prolonged Abdominal Operations.—Dr. Macnaughton-Jones: Notes from the Clinics of Heidelberg and Freiburg.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.).—8 p.m.: Card Specimens. 8.30 p.m.: Papers:—Mr. T. Collins: Adhesion of a Persistent Pupillary Membrane to the Cornea in the Eye of a Cat.—Mr. L. V. Cargill and Mr. S. Mayou: A Flat Sarcoma of the Choroid.—Mr. C. Shaw: Perforating Wound of the Globe with Total Destruction of the Iris and Retention of Vision.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m.: Lecture: Dr. T. W. Eden: The Value of Local Treatment in the Initial Stages of Puerperal Infection.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Fungous Diseases of the Hair; III., Favus; IV., Leptothrix.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.).—5 p.m.: Lecture: Mr. R. M. Leslie: Opsonins.

FRIDAY, DECEMBER 14th.

CLINICAL SOCIETY OF LONDON (20 Hanover Square, W.).—8.30 p.m.: Papers:—Mr. B. G. A. Moynihan: The Mimicry of Malignant Disease in the Large Intestine.—Mr. J. P. Roughton: A Case of Rupture of the Diaphragm.—Mr. J. Berry: A Case of Traumatic Hernia through the Diaphragm.

EPIDEMIOLOGICAL SOCIETY (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Paper:—Dr. C. Brown: On the Distribution and Nature of Sprue, with Notes on the Pathology of Intestinal Dyscrasias.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.:—Mr. A. Lawson: Clinique. (Eye.)

THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11 Chandos Street, Cavendish Square, W.).—5 p.m.: Discussion on Rickets (opened by Mr. L. S. Dudgeon, Dr. F. J. Poynton, Dr. W. A. Milligan, Mr. H. Betham Robinson, Dr. Robert Hutchison).

Vacancies.

The Middlesex Hospital, W.—Medical Officer and Registrar. Salary £100 per annum, with board and residence. Applications to F. Clare Melhado, Secretary Superintendent.

Corporation of Sheffield.—Fever Hospitals.—Junior Assistant Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to H. Sayer, Town Clerk, Town Clerk's Office, Town Hall, Sheffield.

Gloucester General Infirmary and the Gloucestershire Eye Institution.—House Surgeoncy. Salary £100 per annum, with residence, board, and washing. Applications immediately to the Secretary.

Plaistow Fever Hospital, London, E. Junior Assistant Medical Officer. Salary £100 per annum, with all found. Applications to the Medical Superintendent, Plaistow, London, E.

Cardiff Infirmary.—Resident Medical Officer. Salary £120 per annum, with board, washing, and apartments. Applications to Leonard D. Rea, Secretary and Gen. Supt.

Newcastle-upon-Tyne Union.—Assistant Medical Officer. Salary £150 per annum, with furnished apartments, rations, and washing. Applications to James Atkinson, Clerk to the Guardians, Union Offices, Pilgrim Street, Newcastle-upon-Tyne.

Brentford Union.—Medical Officer and Public Vaccinator. Salary £160 per annum. Applications to William Stephens, Clerk to the Guardians, Union Offices, Isleworth.

Appointments.

CUNLIFFE, E. N., M.D., Ch.B.Vict., M.R., B.S.Lond., Honorary Assistant Physician to the Manchester Royal Infirmary.

DAVIS, WILLIAM HENRY, L.R.C.P.Lond., M.R.C.S., Medical Officer for the Fourth District by the Devonport Board of Guardians.

GREEN, E. F. S., M.D.Glasg., House Physician at the Royal Infirmary, Manchester.

KEMBLE, A. C., L.R.C.P. and S.Edin., House Surgeon at the Eccles and Patricroft Hospital.

LANDER, CHARLES LLEWELLYN, B.Sc., M.B., B.S.Lond., L.R.C.P. Lond., M.R.C.S., Honorary Assistant Surgeon to the Royal Albert Hospital, Devonport.

LEAH, THOMAS NOY, M.B., B.S.Lond., L.R.C.P.Lond., M.R.C.S. Honorary Surgeon to the Royal Albert Hospital, Devonport.

MICHELL, JOHN CHARLES, M.R.C.S., L.S.A., Medical Officer and Public Vaccinator for the Fourth District by the Chipping Sodbury (Gloucestershire) Board of Guardians.

MOXON, F. H., M.B.Durh., Assistant House Surgeon at the Gloucester General Infirmary and Eye Institution.

REYNOLDS, ERNEST, M.D.Lond., Honorary Physician to the Royal Infirmary, Manchester.

ROLSTON, THOMAS RESTARICK, L.R.C.P.Lond., M.R.C.S., Surgeon to the Provident Dispensary in connexion with the Royal Albert Hospital, Devonport.

SANDFORD, GEORGE CALROW, M.D., C.M.Edin., Medical Officer to the Workhouse by the Devonport Board of Guardians.

SUTHERLAND, D. P., M.B., B.S.Lond, House Physician at the Royal Infirmary, Manchester.

Birth.

CRICHTON MILLER.—On Dec. 7th, at Villa Mary, San Remo, the wife of H. Crichton Miller, M.D. (San Remo and Aviemore, Inverness-shire), of a son.

Marriages.

ENNALS—ABBOTT.—On Dec. 6th, at Holy Trinity Church, Wallington, Surrey, Lieut. Charles Cutlack Ennals, R.N., son of Dr. C. T. Ennals, J.P., of Louth, Lincolnshire, to Rosalind Mary Abbott, elder daughter of Alfred Hillier Abbott, Beaumont, Wallington.

FOSTER—MALLAM.—On Dec. 8th, at S. Saviour's Church, Torquay, Edward Cecil Foster, M.R.C.S., L.R.C.P., of 179 Banbury Road, Oxford, eldest son of Edward Alexander Foster, I.S.O., to Agnes, third daughter of James Mallam, of Lamberhurst, Torquay.

MARTIN—HARLEY.—On Dec. 8th, at St. Stephen's Church, Philip Street, Sydney, New South Wales, Arthur Anderson Martin, M.D., Ch.B., F.R.C.S.Edin., Fitzherbert Street, Palmerston North, New Zealand, to Constance Margaret, only daughter of the late Alexander Harley, and of Mrs. Somerville Brown, Invertruim, Hassocks, Sussex.

Death.

WILLIS.—On Nov. 26th, at Asheville, North Carolina, U.S.A., Francis Willis, M.D., second son of the late Dr. Francis Willis, of Shillingford, Lincs., aged 73.

THE MEDICAL PRESS AND CIRCULAR.

NOTES AND COMMENTS.

Infectivity of Consumption.

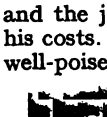
THE infectivity of tuberculosis appears to have got a strong hold on the imagination of people, and from the most utter laxity with regard to tubercular patients, they have now rushed to such an extreme that it is difficult to find a place where the poor consumptive is not taboo. The village of Eldwick is in a state of ferment at present because a sanatorium has been opened in its neighbourhood, to which the tubercular patients of the Bradford Board of Guardians and others are being sent. Why no steps were taken before is not clear, but now that the institution is open an indignation meeting has been held in which loud protests against this standing menace to the health of the village were made. The Chairman quoted the words of Dr. Munro, who promulgated the scheme, to the effect "that consumption was a most dangerous and insidious disease, and ought to be put on the list of notifiable diseases," and put a resolution that the village had a serious grievance, which was carried with only two dissentients, to wit, the medical officer and the matron of the sanatorium. It really seems time that another campaign should be started to teach people in what the danger of tuberculosis consists.

Sycosis or Impetigo.

IT is pretty safe to say that when lawyers get hold of a medical case they generally make a mess of it. True as this is of the High Court, the fact is still more evident in the County and other minor Courts. A case was tried at Exeter County Court last week before Judge Lush, in which a labourer sued a barber for shaving his chin so negligently that he contracted a disease, said by his doctor to be sycosis and by the defendant's to be impetigo. It was explained to the judge that if it were sycosis the fungus must have been inoculated by the barber's ministrations, whereas if it were impetigo it might have been contracted in other ways. Without referring to the question of diagnosis, which surely could have been settled in a few minutes by the microscope, it may be remarked that the point of the case really was whether the barber did or did not cause the disease through the use of dirty razors. His Honour thought otherwise. He laid down the new principle in English law that if a barber held out inducement to people to come to get shaved, he did not imply any warranty that it should be a safe shave. We can forgive the judge his want of knowledge of bacteriology, but not his ignorance of common law. The point has been made over and over again, that a man who undertakes to perform any service does undertake to exercise a reasonable amount of skill and care in its execution. We do not assert that the barber could have prevented the disease in this case, for we do not know all the circumstances, but he would certainly be liable if negligence could be proved.

Exhumation and a Will.

So many and so unjust are most of the accusations made against medical men, and so transparently unfair are most of the actions brought against them in the pursuit of their profession, that it is a peculiar pleasure to be able to congratulate a confrère when he is able to establish his reputation in a court of law. A short time ago we were able to felicitate Dr. Adams, of Buckhurst Hill, on the triumphant vindication of his professional acumen in what was known as the "Exhumation Case." The bias against Dr. Adams, however, displayed by Mr. Clarke in that instance showed itself again last week, when the former, as executor of the deceased lady's will, sought to propound it. Mr. Clarke contended that the will was not legally executed, and that the testatrix was of unsound mind. The amount of the estate was comparatively small, some £2,500, and after the payment of a legacy of £1,500 to a neighbouring church, and incidental expenses, the residuary estate was left to Dr. Adams. The latter amounted to about £200, and the natural man would think that sum a reasonably small amount for one friend to leave to an executor for his trouble. Mr. Clarke seemed to be disappointed that he was left out of the will, and the former insinuation against Dr. Adams having failed, he now took this form of inconveniencing him. Needless to say, the jury found for the will, and the judge very properly awarded Dr. Adams his costs. Would that justice were always equally well-poised in medical cases!



A "MOTOR-EXPERT" who was before Judge Stevenson in the Penrith County Court last week, or rather who should have been, put in an extraordinary medical certificate. This document announced that the defendant was "still out of danger, and unable to attend the Court." As the certificate was signed in the name of a registered practitioner it was impossible to ignore it, but we are glad to

note that the judge had sufficient regard for the general education of medical men to pronounce the certificate "obviously fraudulent." He adopted the wise course of granting a stay of execution, and telling the defendant that if no explanation was forthcoming he would be arrested. The latter, therefore, would seem not yet to be out of danger, in spite of his grandiloquent and "obviously fraudulent" certificate to the contrary.

LEADING ARTICLE.

THE LAY PRESS AND CANCER CURING.

In the *Pall Mall Gazette* last week appeared an article entitled "The Approaching Conquest of Cancer—Authoritative News," by C. W. Saleeby, M.D., F.R.C.S. Edin. It was written in boastful, flamboyant style, freely interspersed with references to reports from America, cables, and all sorts of exciting details about the writer's unique opportunities and private information, in spite of the opinion expressed in his opening sentence that what he had to say needed "no introduction or ornament." Now as this article was written by a medical man, and as it is precisely the most objectionable kind of article that can be written, namely, one booming in a lay newspaper a particular treatment still in the early stages of its consideration by the medical profession, we feel bound to criticise it closely. Dr. Saleeby started by speaking of a case of cancer cured by trypsin, which was published on November 24th in the *Medical Record*, a New York journal of deservedly high standing. Then he said he had heard another case was shortly to be recorded, and that Professor Morton, of New York, was about to send to the same journal a preliminary report on the treatment which was "much more sanguine" in its nature than had been anticipated. Dr. Saleeby then proceeded to plume himself on the fact that he wrote on this subject in "My Scientific Notes" on February 9th and on various later occasions that he "introduced it to all concerned in America," and that "if there is nothing to record from this country where Dr. Beard"—whom he mentioned as recommending the treatment—"lives and works, the fault is not his nor mine." Moreover, he adds, "since January 20th when Dr. Beard published his cases of cure in the mouse, not a case had been recorded here—*successful or unsuccessful.*" As to the accuracy of these statements it can only be said that Dr. Saleeby's other occupations must have been such as to place him entirely out of *rapport* with current medical work. We express no opinion on the value of trypsin—we have seen far too many remedies tried in inoperable cancer to make either sanguine or deprecatory comments on one that is still under trial and shows some encouragement in some directions—but it is common knowledge among all well-informed medical men that trypsin has been tried freely during the past year, and that several practitioners are pursuing their observations on it at the present moment. They owe nothing to Dr. Saleeby and his "Scientific Notes," having acquired their information where that writer has presumably failed to look for his, namely, in the current issues of medical periodicals and in recently-published books on the subject. Having committed himself in this egregious manner, Dr. Saleeby reproduces "without a moment's delay" Professor Morton's comments on the cases treated. These comments are very fairly worded, the strongest expression used by Professor Morton being that two cases were "cured to date," but as he had only been working with trypsin for a few months, such a statement has of course a purely tentative value, and Professor Morton, indeed, does not make any higher claim for it. It is otherwise with Dr. Saleeby. "I offer no vestige of an apology for the means I am taking to bring this matter before the public and the profession. . . ." "If an Englishman's work, bruited in America by me, can save despaired-of lives there, why, in the name of the Eternal, not here also? . . ." "My present business is to take advantage of my early knowledge for the sake of those whom it may serve." To use a lay paper for the purpose of publishing expressions of this kind is as improper as it is unbecoming, and in the next two numbers of the *Pall Mall* the hollowness and folly of the whole business was exposed by interviews with cancer hospital authorities, by whom it was revealed that trypsin had been tried both at the Middlesex Hospital and at the Cancer Hospital, and had proved disappointing in their hands.

Now the question of writing articles signed by medical men for the public press is always a delicate one. There is, we ourselves believe, a useful function for such articles to perform, namely that of educating people to take reasonable views of medical questions. But, if written, they should be most carefully worded, they should eschew anything in the nature of sensationalism, and they should show that the writer seeketh not his own. In a word, they should be the exact antithesis of the one we have mentioned. True, Dr. Saleeby says he does not practise, but that fact does not give him a free hand as regards professional traditions and professional ethics, so long as his name remains on the medical register. He says anyone who wishes to attack him is heartily welcome, and speaks of having been "snarled" at in America, with regard to his effusions on this subject. Well, we say that a writer who takes it upon himself to flout medical opinion by laying before the public a hope of cure from such a disease as cancer, on lines which have not the support and sanction of the profession, incurs a grave responsibility, and that when he is himself a medical man that responsibility is ten times heavier. The general result of such a course is to lead patients to dally with drugs till the time when the knife might cure has passed, and thus to conduce to their suffering and death. There are perfectly proper channels for bringing new facts and observations before the profession, and there are legitimate methods

by which new treatments may be tried. But when these safeguards are removed and immature conclusions are put before the public, cruel and bitter wrong may be done. A member of the medical profession who acts thus owes his profession an ample apology; that is, if he wishes to retain its respect.

NOTES ON CURRENT TOPICS.

Plum Pudding.

Raisins this year stand at famine prices, but that will not for a moment hinder the yearly output of many hundreds of tons of English plum pudding. All round the world will these dainty products travel, their solid frames compact with sweet nourishment and fragrant with odours of home and hearth. In these days of faked food and tinned horrors plum pudding forms a veritable sheet anchor for our shaken faith. Its genius is the very personification of purity and solidity. What say you of bread and flour and beer and suet and candied peel and currants and raisins and brandy and other good things all conglomerated into one fair round mass of unsurpassable comeliness? Were all the learned professors of the Royal Society to lay their heads together they could not hope to rival the simple beauty of form, the rich odour and colouring, the toothsomeness, the condensed nourishment and the digestibility that form part and parcel of this "speckled globe of savoury delights." Nor could science give us a more perfect method of sterilisation than that of boiling for hours and hours in a basin, so that twelve months later the pudding can be shaken out still sweet and wholesome, but a trifle mellower with age. Verily, the origin and progress of plum pudding mark the triumph of English brains in days when there was no science at hand to fill our minds with daily forebodings about our meat.

Violet Leaves and Cancer.

A London newspaper recently published the gist of an interview with an aged ironworker, who declared he had cured himself of cancer by the application of violet leaves. The journal in question, the *Morning Leader*, has assumed a great and serious responsibility in publishing statements of this kind. The man in question said in 1904 he had undergone four operations for cancer in the lip and throat. Some time ago he began the violet cure, drinking an infusion of the leaves and applying the leaves as a hot poultice. After six months his "cancer" was cured. Now, if that be the case—if there be no loophole of doubt as to the absolutely cancerous nature of the complaint, and that being proved the second point of "cure" be also established—then the *Morning Leader* has witnessed a miracle that has escaped the medical profession, in spite of its accumulated wealth of experience in such diseases, and of the incessant eagerness and high technical skill with which they are pursuing the subject day by day, year in and year out in laboratories, hospitals, and *post-mortem* rooms. we wonder did no gleam of scientific doubt penetrate the interviewer's brain when he sat talking to the "aged ironworker." We most of all wonder what was passing through the mind of the accomplished editor of a London newspaper when he permitted such sorry and misleading matter to slip into his columns.

Nine Miles of Protest.

On the 13th instant the Member for Anglesey presented the House of Commons with an enormous petition from members and supporters of the National Canine Defence League. The energy of the honourable gentleman was duly recognised by the cheers of the House when he stated that the document consisted of nine miles of parchment, weighing a quarter of a ton, and subscribed to by 400,000 signatories. The petitioners set forth that they were opposed to the vivisection of dogs, and prayed the House to pass a Dogs' Protection Bill, which should prevent those animals from being made the subject of experiment. Clearly it is simply from sentimental feelings that the exemption of the dog is demanded. At the present moment highly important observations are being made on cancer in dogs. Would the supporters of the petition, we wonder, if faced with this issue, venture to throw any obstacle in the way of probing to the depths one of the most fearful scourges of mankind? It may be wondered how many miles of parchment would be forthcoming in protest against, let us say, hunting carted deer, coursing rabbits, shooting trapped pigeons, plucking feathers from live birds, crimping living fish, or the countless cruelties that are every day committed in pandering to fashion, spurious sport, and other merely selfish pleasure and vanity. Yet any experiment performed upon a dog is an unselfish attempt to succour and aid suffering humanity—the highest and most transcendent of all conceivable human aims.

A Chance for the "Youngster."

We lately had the pleasure of reviewing Dr. Howard Kelly's Life of Walter Reed, the American Army Surgeon whose final glory it was to establish the specific relationship between the mosquito and yellow fever. The full effects of that discovery have not yet been reached, but already its enormous practical importance in the prevention of yellow fever has been demonstrated again and again. It is then only fitting that Reed's colleagues should have recognised his services to humanity by raising a memorial to him. At the end of last month a bronze tablet, suitably inscribed, was presented to the King's County Hospital, where Reed received his medical education, and a dinner was given in honour of the occasion. Dr. Howard Kelly was the speaker of the evening. and after a warm eulogy of the hero, he addressed some wise and straightforward remarks to his audience. Speaking of Reed's example and their enthusiasm for his memory, he said he wished his hearers to resolve to profit by them, and especially to seek to copy his spirit of uniform kindness and consideration for others, both rich and poor. To the physicians and surgeons he said that they should seek to train their students to take their places, and when they were ready, the older men should be ready to step aside and let the

youngsters have a chance. The advance of the young man should be looked on with affectionate interest and not with jealousy, and the young surgeon should be given every chance to operate. When his pupil was efficient, the teacher should be ready to resign part of his work to him, and with the leisure thus gained devote more time to study. He held it to be an iniquity for one man to hold so many hospital appointments as to keep him constantly busy. Which shows that in America as in England there is on the part of many medical men an acquisitiveness for hospital appointments which is beneficial neither to the profession nor to the public.

Tuberculous Pork as Food.

THE logic of the Britisher may be sound enough in the long run, but it is none the less apt to be extremely slow in reaching its goal. After much expostulation, for instance, it has been determined that portions only of the flesh of pigs may be sold for food when certain defined viscera, *e.g.*, the peritoneum or pleura, are infected with tuberculosis. On ordinary grounds the plain man in the street would ask, if tuberculosis pervade the whole body, what steps are taken to ascertain that the flesh of such animals is absolutely free from the taint of consumption. In the House of Commons various inconvenient questions were last week pressed upon the attention of the Local Government Board. It was stated that in Birmingham tubercular pigs were condemned and destroyed to the value of £100 a week. Mr. John Burns replied that the average destruction was much less than that mentioned, and he had no authority to compensate dealers. He practically admitted that the Birmingham market inspectors condemned animals previously passed by port officials. In answer to a further question the right honourable gentleman expressed a hope that he would shortly be able to bring a Bill before Parliament with the view of ensuring that the carcases of condemned pigs should not be sold for human consumption. This statement points to a solid, if somewhat belated, step forwards in a much-needed direction.

The Halifax Guardians and Medical Sweating.

An instructive object lesson as to the value of united action is presented to the medical profession by certain recent events at Halifax. The guardians of that town have lately given long and earnest consideration to a "serious crisis" that has arisen between their Hospitals Committee and the local medical profession as to the appointment of a resident Poor Law Officer. Founding our statements on a long report given in the *Halifax Guardian* of December 8th, we find that £160 salary was offered during the Boer War, when there was a dearth of medical men at home. After the war it was reduced to £150. What further reductions were made, if any, does not appear, but the next great pertinent fact is that on the recent retirement of a lady medical officer the post was advertised at £100 per annum. The guardians say that there were annual increments of £5 up to £120, but that fact was not mentioned in the advertisement. The attention of the British Medical Association and of its local branch was called to the reduction of salary. In the course of the resulting correspondence the branch maintained that £140 represented the lowest salary that should be accepted for the post. A "warning" was published in the *British Medical Journal* advising any intending applicants to write to the local secretary. The effect of this firm action upon the Halifax Board has been electric. They characterised the letter from the Association as "insulting and reprehensible." They disclaimed any intention of "sweating" the profession and claimed that their rate of pay compared favourably with that of most other unions. A labour member stood up in defence of the medical profession, whose attitude he regarded as reasonable and proper. He wanted to know, amongst other things, why it was "contrary to all notions of fair play" to warn doctors against taking a certain post while enquiries were being made. However, the mystery of the curtailed advertisement was not solved, and the guardians unanimously confirmed their Hospitals Committee report. We understand that they have since seen their way to modify their attitude. The incident shows the unspeakable value of medical unity and organisation.

The Recent G.M.C. Elections.

The recent election of four direct representatives for the General Medical Council offers various points of interest. The precise figures were officially reported as follows:—

Browne. Dr. Henry Langley	4,861
McManus, Dr. Leonard Strong	4,286
Latimer, Dr. Henry Arthur	4,002
Jackson, Mr. George	3,985
Brown, Mr. George	3,773
Smith, Mr. Joseph	2,489
Smith, Mr. Frederick John	2,013
Broadbent, Mr. George Harry	1,785
Renshaw, Dr. Charles Jeremiah	1,080
Rhodes, Dr. John Milson	855

The election is memorable as being the first held under the new regulation, whereby voting by ballot is established. The total number of voting papers issued was 24,659, against 23,473 in 1902. The total number of papers received back was 12,828 or 52.02, of those issued. Nine hundred and eleven letters were returned by the Dead Letter Office, and no less than 1,508 votes, or 12.61 per cent., were invalid owing to the non-compliance with clearly stated directions as to signature, fastening of envelopes, and so on. A more striking commentary upon the unbusiness-like methods of the medical profession could hardly be imagined. Two old and faithful servants of the profession have been dismissed from the Council in the persons of Messrs. George

Brown and Jackson. Dr. F. J. Smith is the only consultant on the list. Messrs. Broadbent, Renshaw and Rhodes appear to have secured mainly local support. In Scotland Dr. Bruce, after some twenty years' service, has been replaced by Dr. Norman Walker.

Carted Stag in a Labourer's Cottage.

The Surrey stag-hunt has witnessed many scenes of cold-blooded barbarity that might well send a thrill of horror through civilised society. The story of the chase of a deer a week ago is a standing disgrace to all engaged in so spurious a form of sport as that of hunting carted deer. On the occasion under notice a pack of hounds and huntsmen chased a deer that fled along the South-Eastern railway line, and narrowly escaped being cut to pieces by a passing train. Upon reaching the outskirts of Redhill she crossed and re-crossed the line several times; and eventually took refuge in the premises of the National Telephone Company. Being ousted thence she darted away and dropped fifteen or sixteen feet into a roadway. Leaping a high wall, the poor affrighted creature rushed into a labourer's kitchen, where she at last found pity and protection. This sort of thing may be considered a manly amusement for sportsmen and gentlemen, but we venture to say it would be roundly described as barbarous brutality and inhuman cruelty by the scientific men who as vivisectors are] branded as simply outside the pale of humanity. Now, let it be asked, if vivisection merits nine miles length of petition to the House of Commons, what length would be required to protest adequately against the naked and unabashed torture inflicted by the hunters of the carted deer ?

Resignation of Poor Law Medical Officer.

The official inquiry into the administration of the West Ham Board of Guardians has led to many unexpected results. Already one of the guardians has committed, and another has attempted, suicide, while others are on their trial for fraud, and a contractor is undergoing penal servitude. In the Infirmary a good deal of wastefulness and laxity was disclosed. The Local Government Board have requested Dr. E Vallance, the medical superintendent, to send in his resignation. Their reason is that the unsatisfactory state of affairs was largely due to the want of proper supervision by that officer, and "his failure to exercise the general administrative control, which is an essential requisite for his position." In a letter to the guardians the Local Government Board observes: "In view of this dereliction of duty, and his laxity in matters under his immediate control, such as the diet of patients and the large supply of alcohol, the Board have arrived at the conclusion, and they cannot properly allow him to retain office, and they have addressed to him a letter, a copy of which is enclosed, requiring him to place his resignation in the hands of the guardians." The guardians decided not to discuss the matter, and they directed the clerk to inform Dr. Vallance of the Local Government Board request.

"Improper Treatment."

It has not been long in coming. In an article last week we pointed out—not that much prescience was needed to do so—that if the jury's decision in the "Cardiff Surgeons" case were allowed to stand, the position of medical men with regard to their patients would be seriously compromised. Sitting last Wednesday, the Board of Management of the Cardifi Infirmary received a letter, in answer to an invitation from them, from an architect, Mr. Hiley, complaining of the treatment he had received as an out-patient at the Infirmary. This gentleman had been knocked down by a passing train some months previously near Ely, and had subsequently been treated for some time at the Infirmary. It is not in the least clear why an architect, presumably possessed of certain means, should have been treated at the Infirmary at all, and this point certainly seems to call for investigation. However, Mr. Hiley having accepted charity, proceeded to complain of his benefactors, as many people do when they get anything for nothing, and a sub-committee which inquired into the charges found, we understand from a report, that there was no foundation in them. Mr. Hiley, it is said, is now prepared to modify his views in the matter. We hope so, but we cannot be surprised at anything in the way of complaints as things now stand at Cardiff.

PERSONAL.

The managers of the Royal Hospital for Sick Children, Edinburgh, have appointed Dr. A. Dingwall Fordyce to be extra physician to that institution.

The only representative of the medical profession who has been awarded a medal by the Royal Society in 1906 is Professor Elias Metschnikoff.

The medical profession is not very strongly in evidence on the Council of the Royal Society under the new President, Lord Rayleigh. The three representatives are Professor David Perrier, M.D., Professor Ernest Starling, M.D., and Augustus Waller, M.D.

Pius X. has decided that Dr. Lapponi's successor shall be his old friend Professor Davenezia, of Venice, who was formerly Cardinal Sarto's physician.

Dr. Acland, having been appointed by the Royal Colleges of Physicians and Surgeons Official Visitor to the examinations of the Cairo Medical School, has left London for a few weeks in connection with the appointment.

The formal distribution of the Nobel prizes took place at Stockholm on December 10th to the following recipients:—Professor Moissan, of Paris (chemistry), Professor Thomson, of Cambridge (physics), Professor Golgi, of Pavia (medicine), and Professor Ramon y Cajal (medicine). All these received the prize diploma and a gold medal from the King in person. Professor Giosuè Carducci, of Bologna (literature), was absent, Count Caprara, the Italian Chargé d'Affaires, acting as his proxy. Each prize this year amounts to 191,480f. (£7,659).

A CLINICAL LECTURE
ON
DEFECTS IN DEVELOPMENT: THEIR SIGNIFICANCE. (a)

By FRANCIS WARNER, F.R.C.P., F.R.C.S., M.D.,

Senior Physician to the London Hospital, the Royal Albert Orphan Asylum, &c.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—If you go into the Surgical and Orthopædic Departments, you will see a large number of cases of congenital defect, of one kind and another, in gross form, mostly requiring surgical treatment: such cases, for instance, as clubfoot, cleft palate, harelip, possibly others of defect of the ear, congenital dislocation of the hip-joint, hemiplegia, and a number of cases of gross defect, which at once, and obviously, attract your attention. If you look at any large body of statistics of cases of this kind, the first thing that will strike you is that the larger proportion always falls upon males. I am not going to speak of those gross conditions, but of those cases of minor defects that you will see frequently among any group of children.

The proportion of children that have some condition of ill development is very large, and, as I have said, it falls mainly upon the males. In the course of an extended inquiry that I made personally in schools, when I had the opportunity of observing one hundred thousand cases during a series of years, and taking notes of them, this fact that I speak of came out very markedly. In putting the total results of that inquiry together, we found in looking over large numbers of children congregated in schools that, of the boys 8.7 per cent. showed some condition of defect in development, and of the girls 6.8 per cent.

Let me explain now what you should look for in a patient to satisfy yourself as to whether or not the conditions of development are up to the average or normal. Looking at this boy (a patient from the wards) we want to see whether he is a well-made boy or not, as apart from any question of medical diagnosis. The first thing to look at, and the most important of all, is the head. You will gain much information by the use of the tape-measure. The most important measurements to take are three. First of all, you should ascertain the circumference of the head—that is to say, the largest circumference that you can get. This boy is seven years old, and the circumference of his head is only a little over 20in. As to the normal circumference at birth, it should be about 11in.; at nine months, that is the time of dentition, when lactation should cease, it should be 17½in.; at the end of the first year 19in.; at seven years, when, in the generality of cases, school life has begun, 21in. This standard of measurement is higher than what one usually finds amongst hospital cases. Speaking for Buxton children's ward, nearly all the cases are small-headed. You may take another measurement of the head, the transverse, from the top of the meatus auditorius, over the vertex, to the top of the meatus on the other side. Another useful measurement is from the bridge of the nose, or the upper terminus of the nasal bones, to the occipital bridge. It is very important to watch in growth of the child not only the increase in the circumference of the head, but also the increase in the transverse measurement. There is very little difference between the transverse measurement and the occipito-frontal. In a well-made head the measurement from back to front should a little exceed the transverse measurement.

Having considered the question of the size and volume of the skull, let us turn our attention to other parts of the head. With regard to the face: the eye openings, or palpebral fissures should be sufficiently large, wide, and high, and long from side to side. Another item of normality about the palpebral fissures is that the axis of the two is in a straight line. We sometimes get a condition that is said by some to be a reversion to an earlier type of manhood, in which the transverse axis, instead of being horizontal, may slope outwards and downwards, or in other cases it may slope upwards; but the principal point, perhaps, is that of size.

It is important to observe the mouth and the nostrils. The principal point about the mouth is that it should be large enough. It is very common to have a small mouth in the male, and it is also very common to have a mouth which is kept constantly wide by grinning. A small mouth is frequently accompanied by a narrow and contracted palate, and by conditions causing obstruction to the nasopharynx predisposing to deafness.

Concerning the palate, what we like to see is a palate of good width, and the front of it well rounded. The common defect is that, instead of being well rounded in front, it is contracted laterally, and comes to a sharp angle in front, often spoken of as "V-shaped." This means that the anterior portion of the jaw on either side comes to the front in a sharp angle instead of a curve. This is a point of great importance, for, next to the condition of defective skull, the palate gives the greatest indication of the constitutional tendency of the individual. Professor Keith has gone over this matter very carefully with me, and has taken casts of various cases of defective palate, and analysed them. He concludes that in these cases of narrow and V-shaped palate, the condition is one of defective development in that portion of the upper jaw in which the milk teeth are produced, leaving out that portion in which we have the permanent teeth. This condition of narrow and contracted palate often goes along with nasal obstruction—such as enlarged turbinates, adenoids, and large tonsils and also, in female adults, with a form of dysmenorrhœa. So that, in adolescence, if you see a case of narrow and contracted palate, you should inquire as to whether there is any indication of stenosis of the os uteri giving rise to dysmenorrhœic symptoms.

The lower jaw should be in proportion to the upper. There are two common defects about the lower jaw; it may be too large when compared with the upper jaw, or it may be extremely small in comparison with it.

In regard to the nose, it is essential, for the purpose we have in view, to look separately at two parts of it—the bony nose, made up of the nasal bones, and supported inside by the septum, and the cartilaginous portion. A great deal of misunderstanding arises from not looking whether the defect is in the bony portion or in the cartilaginous portion of the nose. It is of comparatively little importance whether the cartilaginous portion is badly grown or not. A much more important question is, Are the nasal bones fully developed? In the infant the nasal bones are extremely small, and their development may be late, sometimes not beginning until the child is from one to two years of age. At seven years of age you may find the nasal bones still very short, making a small bridge to the nose, and giving it a very different appearance from one that is well developed. I have known many cases in which nasal bones have been very short up to seven and remaining so till between seven and ten years of age, although the cartilaginous portion has grown to its normal size. A boy, in such case, would have what is known as a tipped nose. It is not that the cartilaginous portion is bad, but it means deficient breathing.

(a) Delivered at the London Hospital, Oct. 31st, 1906.

We come next to the external ears. They very often have defects, but the defects are amongst those that fall in greater proportion on the boys than on the girls, being five or six times as frequent in the one case as in the other. What are the common defects of the external ear? First of all, the ears are generally symmetrically affected. There are criteria by which you can judge whether the ear is normal or not. First, are all the parts of the ear seen? Secondly, is the tissue of which the ear is composed healthy, normal tissue? This boy has got a well-formed helix. That is important. Thirdly, is the skin of the ear healthy? He has a nice, healthy ear. There are no little varicose or dilated veins about it; the skin looks of a normal colour, and you can pick it up, showing that it is not adherent to the cartilage. The tissue of the ear is normal in structure and size. A very common, and also very important, defect about the ear is an absence of the antihelix. This boy has got no antihelix. There you see a typical outstanding ear. If the antihelix is absent you get an outstanding ear. An outstanding ear is apt to be defective both in structure and tissue. The antihelix may be absent on one side or the other, that does not affect the hearing; an outstanding ear, without an antihelix, is often very good for collecting sound. It is said that in the advancement of man, in the process of evolution, things have gone on for the best; but let me point out that, amongst the lower animals, the donkey has not got an antihelix; its ears stand out, and are much better organs for collecting sound than the human ear.

Those, then, are some points of interest as indications of defective development.

The hand should also be examined. The fingers may be too long or too short, or there may be webbing of the fingers, or an excess of subcutaneous tissue on the palm of the hand, or an abnormality in the palmar markings. In some cases of defective development you find the marks which are totally different from those on the hands of ordinary people. Professor Keith has had impressions taken on paper of some of those markings on the hand, in cases of defective development, and analysed them, and shown that sometimes they correspond with those of lower animals.

There is a defect, called the epicanthis, which is not uncommonly found in the face, and consists of a vertical fold of skin projecting in front of the canthis in the inner portion of the eye openings. This is a defect of the Anglo-Saxon race, and a great deal has been said about this. The epicanthis is one of those defects which, in many cases, disappear before adolescence; many a child that has had epicanthis at five years of age has lost all trace of it when old enough to go into society.

Turning our attention once more to the ears, you may sometimes find just below the pinna a little cartilaginous growth. This appears usually on one side only, and is homologous to a supernumerary ear. This is important, because it may show a great tendency to grow rapidly.

I want next to speak of the significance of these minor indications of subnormal development. I pointed out to you that there are a large number of cases which show some point of subnormal development; but do not go away with the impression that, because there is some point in development below the normal, therefore the child is a defective one. I only say that the defect is worth noticing. Let us compare those individuals who have some condition of defective development with those who are perfectly normal. Taking the cases that had some of these conditions of defective development, we found, on further examination, that 22 per cent. of the boys were thin and pale, and delicate. Taking similar cases among the girls, 32 per cent. of them were pale, thin, delicate children. If you are dealing with children who are pale, thin and delicate, and yet have no condition of disease, you will find that a large number of them are cases such as I have been speaking of to-day, cases which show that their bodily growth has been imperfect in certain features. This law applies much more to girls than boys. A boy, with some condition of defective development, may go on in fairly good health, but a girl is much more likely to become thin, pale, and delicate, and then anæmic. These girls also tend to develop abnormal nerve signs, to fall into a condition of anæmic low nutrition, nervousness, and mental dulness, until they get into those grave conditions frequently seen in young womanhood, namely hysteria, or neurasthenia. I told you just now that, of the cases we examined that had some defect in development, 22 per cent. of the boys, and 32 per cent. of the girls were thin and pale and delicate. The percentage of boys suffering from irregularities of the nervous system was 36, and that of the girls 35, or almost the same. As to the condition of dulness, the percentage was the same in each case, namely, 31 per cent.

Perhaps an active, first-class "M.A." mistress of some girls' high school says, "The girls are as good as the boys, and a little better; they can work, and stay on at school, and matriculate." But, if you are practising in that town, you will have a great many more children patients delicate, and pale, and thin, and falling into conditions of ill-health among the girls than among the boys. That mistress is speaking of her girls on the average, and she says they can work well. True, but what about the percentage of her girls—about 6 per cent.—who have some condition of defective development? They would be known to you. And when the question is raised, concerning some girl, "Is she strong enough for a 'hare and hounds' race on Saturday afternoon?" her mother says, "She is not strong enough!" If it is one of those cases that are not perfectly good in those points of development that we spoke of, then there at once is a reason for being cautious. With regard to a high school, if you take a list of all those who present some condition of defective development, and then ascertain how many of the children left in the school show signs of delicate health, you will not find more than one to two per cent. But if you look at those on your list, those who have some condition of defective development, about one-third of them will betray a low state of health—they will look thin, or nervous, or dull, or anæmic. I think, therefore, you will recognise the importance of the practical points that I am speaking of.

I have a point to impress on you. Of the children that come into our medical wards we scarcely find any that are free from defect. The commonest defect is small head. Other defects that I have mentioned are also frequent. Children come in with a diagnosis of "marasmus." If the case is one of "rickets," it will be admitted as such. The large number of cases in Buxton Ward mostly show some condition of defective development, usually a condition of small head. It is those children who have some imperfect development from birth that tend to fall into a condition of low nutrition, bronchopneumonia, and other diseases which fill the wards.

Taking it that all the children in Buxton Ward are defective, let us look at the admissions during last year. There were 265 boys and 228 girls admitted into the ward during that time. I venture to say that the cause is not that those who admit patients into the hospital have any special desire that these should be boys, there is no question of male or female beds in Buxton Ward; it must therefore be a question of demand, and more males than females come in. Of the boys, 67 died during the year, and of the girls 65, representing a percentage of 25 and 30 respectively. We are looking then at the mortality of what may be termed a selected body of children with some degree of imperfect development, and you see that the percentage of deaths among the females is much greater than among the males. Bear that in mind. Looking at school life we find that, of those who have defective development, the tendency to become thin, and pale, and delicate falls greater upon the girls than on the boys. And so, in Buxton Ward, where all the children patients have some defect in development, you find that the tendency to death falls much more on the girls than on the boys.

As to the birth-rate, a larger number of male infants are born than female. At the end of the first twelve months of age, the number of female babies exceeds that of the number of male babies. The infant mor-

tality, of which we hear so much, and which is so exceedingly important, is, to a great extent, a matter of deaths amongst the males, because there are born so many more male infants with conditions of imperfect development. If a child has died during the first year of life, it is certified as a male or female; but for our present purpose the great question is, Was it a normally made child, had it a fairly developed head, and a sufficiently good brain inside? Though a larger number of males are born than females, yet owing to the much higher proportion of cases of defective development amongst males, the mortality that marks the latter leaves a considerable surplus of females in adult life. Not only in adolescence are there more women than men, but the women have had the best of it in infancy in having been better born, and, moreover, they live, on an average, some three or four years longer than men; that fact is borne out by the census reports. There is a very large preponderance of females, and a female life costs much more in providing for annuities than a male life. A thousand pounds utilised for the annuity maintenance of a man over sixty years of age would bring about £4 10s. per cent.; the same sum of money invested for the benefit of an old lady would not bring more than £3 10s. per cent., because she will probably live so much longer.

I have brought before you some points which I think it is of very great importance that you should watch while you are at the hospital, and I am sure they will become matters of considerable interest and importance in practice when you take charge of family interests yourselves. They will enable you, among other things, to make a better selection of those children who are delicate and those who are not delicate. Amongst the delicate class of children I include those who, though they do not suffer from any particular pathological condition affecting any one organ, yet, nevertheless, often have headaches, or feel tired, or get a little pale, or fall off a little in their appetite—trifling things which a mother notices, but which do not very much affect their future condition of health. A child in any of these conditions is delicate, in a sense, but often enjoys really good health.

NOTE.—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week's issue will be by Professor F. Lejars, M.D., of the Faculty of Medicine, Paris, on "The Differential Diagnosis of Typhoid Fever and Appendicitis."*

ORIGINAL PAPERS.

THE TREATMENT OF BRONCHIECTASIS.

By EDWIN ASH, M.B., B.S., London,
Sometime Resident Anæsthetist and House Physician to St. Mary's Hospital, W.

THE problem met with when we come to consider the treatment of bronchiectasis is unique in therapeutics.

At first sight it is apparently a condition eminently suited to surgical measures, namely, the presence in a viscus of numerous cavities filled with a fœtid secretion which has difficulty in escaping. And yet when the statistics are examined it is found that in the majority of cases surgery has failed utterly.

The indications for treatment, as tabulated by Dr. Ewart, are as follows:—

1. Emptying of the cavities.
2. Relief of the fœtor.
3. Reduction of catarrh.
4. Protection of membrane from further inhibition.
5. Diminution in size of dilatations.
6. Improvement of respiratory functions in general.

And it will be well to consider at once why surgical methods have failed in this instance, and to see if the results obtained hold out any hope that these methods may be successful in the future.

Trzebiski published a series of cases in 1892 showing that, with 12 operations for bronchiectasis, he had no complete recoveries, 8 deaths, 3 lost sight of, 1 so far doubtful.

In the same year Hofmokl's statistics were almost as hopeless; out of 14 operations he had only 2 complete recoveries.

And an examination of specimens of bronchiectatic lungs shows why this should be the case. It is not one large cavity, or even a series of communicating cavities, that has to be dealt with, but a number of isolated cavities burrowing throughout the lung, each being a focus for toxic absorption, and each unaffected by the cure of its neighbours.

The few successful cases are those in which the symptoms have been almost entirely due to one large cavity. If this is accessible, then operation is desirable, and a fortunate ending may be looked for. But in the majority of cases, with numerous burrowing cavities, operation holds out little hope of cure, although sometimes an improvement may be obtained by draining one, or even two, of the largest collections.

As regards the technique of such operations, it is generally agreed that it is best to make a very large opening into the chest wall, having previously localised the affected area with an exploring syringe. Then if adhesions have not been found between the two layers of the pleura so as to shut off the field of operation from the general pleural cavity, it is absolutely necessary to postpone the remainder of the operation. In the meantime, formation of the necessary adhesions is ensured by incising the parietal pleura and suturing the two layers together, as advised by Réclus. After five days or so the second stage may be proceeded with. It has been shown by results that otherwise empyema and pyopneumothorax are very liable to follow.

The actual incision of the lung tissue should be made with a Paquelin cautery, heated to a dull red. This seals most of the blood-vessels as it divides them, and prevents hæmorrhage that tends to be very serious, and possibly fatal. The draining of the cavity is then carried out by soft rubber tubes, but it is a point of great importance to note how emphatically the authorities on this operation protest against irrigation, several cases having been reported in which pneumonia resulted from such a procedure.

A consideration of the surgery of bronchiectasis, then, leads to the conclusion that unless the symptoms are very urgent, and at the same time undoubtedly due in the main to some one large and accessible cavity, less radical means must be relied on for the alleviation of the disease. Such measures may be classified into those tending to empty the cavities, those tending to reduce the fœtor, and those tending to repair the damaged bronchi.

Many patients soon find out that they can get rid of large quantities of bronchiectatic secretions by assuming certain postures. And the position from which the greatest relief will be obtained depends upon the situation of the cavity or cavities. A considerable number find that by assuming an inclined position, with the head and chest lower than the feet, the outflow freely gravitates out of the sacculations.

These postural methods should be practised as a routine, and combined with strong expectorant treatment. And, moreover, every few days further relief can be given by the administration of an emetic. In these ways the cavities are regularly emptied, and washed out by a stream of watery mucus.

But as the more severe symptoms, such as pyrexia, rigors, cachexia, and so on, are due to absorption of tissues resulting from microbic activity in the cavity contents, it is even of more importance to make the secretions aseptic than to ensure their expectoration.

Formerly the chief attention was paid to the fœtor, but it is obvious that measures removing the fœtor without being anti-microbic merely beg the question. If the cavities can be freed from "septic" organisms, the fœtor will cease as a consequence, and so it is necessary to find some means by which antiseptic substances can be introduced to the fœtid collections.

Many methods have been tested for this purpose,

inhalations, sprays, intratracheal injections and drugs by the mouth having in turn had their supporters. The difficulty has been to get the anti-microbic agent into the depth of the lung in sufficient quantities to influence the large fœtid cavities that exist there.

Simple inhalations from a jug of vapour impregnated with one of the volatile antiseptic oils may affect the superficial layers of secretions, but utterly fail to disinfect the greater bulk thereof. Now, any real good that is done by this method results rather from the product of cough and expectoration than from any anticipated local influence. These remarks apply equally to methods in which inhalation takes place through a dry sponge steeped in the deodorant mixture, on the principle of Yeo's inhaler. It is possible that inhalations given by a spray may be somewhat more adequate than the former, and both the steam spray and varieties of "nebulisers" have been extensively used. In the one instance large quantities of drugs can be used, but there are great disadvantages inseparable from the use of steam; in the other hand, an "atomiser" so finely sub-divides the oil globules that the actual supply of drug to the patient is very greatly limited.

This method of internal administration of antiseptic drugs fails, however, for although fully worked into the bronchial secretions, they do not reach the chief seat of sepsis, as the mucous membrane lining the bronchiectatic dilatations is so disorganised as to be incapable of physiological action. So that each of the antiseptic agents stops at the point where it is most urgently needed. A list of the drugs so used includes the balsams, copaiba, terebene, tar, oleoresins, and many essential oils, thymol, guaiacol, eucalyptol and creosote. On the Continent myrtol has been used by some physicians, and reported on favourably. Capsules containing these drugs should be taken frequently throughout the day, and by persistent action will undoubtedly relieve the fœtor to some extent.

However, although the above methods fail to do much good, it has been shown latterly that a more thorough application of the same principle will produce remarkable results.

Such are attained by the creosote method introduced by Dr. Chaplin, and to a less degree by Sehrwald's intratracheal irrigation method, and by Poore's saturation of the system with the volatile constituents of garlic.

By continued administration of garlic until the odour was permanent in the breath, very great alleviation of the fœtor and a diminution of discharge has been obtained. The remedy should be taken with meals, so as to minimise the inconvenience to the patient. The active essential oil of this plant contains sulphide of allyl, which is probably the active agent, and oil of allyl may be given in half to three minim capsules, three times a day. But excellent as the results obtained have been, this method does not bring about an emptying of the cavities, and so can produce no permanent benefit.

Intratracheal injections have been frequently used with success, but the disadvantages of such a method are numerous and obvious.

Usually one drachm of a mixture containing ten parts menthol and two parts guaiacol and 88 parts olive oil was injected through the glottis by a hypodermic syringe; the disinfectants reached the lungs through the medium of the trachea to varying extent. In this case also the method does not assist the emptying of the cavities, although it may give great temporary relief to the patient.

By far the most successful of these more thorough methods is Dr. Chaplin's plan of getting the patient to inhale an atmosphere permeated with creosote vapour to an extent which causes violent coughing and consequent expectoration of large quantities of secretion. At the same time, the creosote must be present in sufficient quantity to adequately disinfect the emptied cavities.

To attain both these ends a high degree of concentration is required, so that the inhalations can be borne only for a short time at first. Moreover, the vapour is extremely irritating to the conjunctival and nasal mucous membrane, so that means have to be taken to protect these parts, if the treatment is to be borne with any degree of comfort. In hospitals, when this method is made use of, a special inhalation chamber is prepared; it should be small, and as air-tight as possible. The creosote is vaporised from a metallic evaporating dish, which should have some stable support, otherwise a conflagration may ensue.

At first the patient can only bear a few minutes' exposure to the atmosphere of such a chamber, even when his eyes are protected by goggles and his nostrils plugged with cotton wool. But in a short time the process is got used to, and an hour's inhalation can be borne daily.

The cough produced is exceedingly efficacious in rapidly clearing the cavities of the most tenacious secretion, which at the same time is possessed of a horrible fœtor. Less spontaneous expectorations occur each morning as improvement results, and in about five or six weeks' time the cavities are cleared and disinfected, so that the final stage of recovery can proceed, and consists in the gradual contraction of the sacculations.

Numerous successful results have been published since the introduction of this method. The author has seen several instances of remarkable improvement following creosote inhalations at the Brompton Hospital.

Dr. Doble published a full account of one such case in the "British Medical Journal" some ten years ago (June, 1896), in which the course of disease and the effect of creosote inhalations were very clearly shown.

The patient was a man aged forty years, whose chief symptoms were progressive emaciation, paroxysmal cough, expectoration of fœtid sputum, sweating, languor, and an irregularly remittent pyrexia. It is noteworthy that with regard to physical signs Dr. Doble wrote:—Physical examination of the chest elicited no very definite signs beyond some coarse crepitations, which were usually to be heard at various parts of the lungs." He diagnosed the case as one of long-standing atrophic bronchiectasis, and began the treatment with inhalations of eucalyptus oil (dr. ss. to the inhaler) twice a day. Potassium iodide and terebene were given internally. But no improvement followed, and it was decided to try Chaplin's creosote method. This was carried out in accordance with the description already given, and at first the patient could only stand ten minutes in the chamber, owing to nausea and violent cough. However, he got used to it in a few days, and inhaled the concentrated vapour one hour daily for three weeks. Improvement took place from the very first, and after the first short inhalation even the cough was improved, and the temperature, which had been rising, and had reached 101.4 deg., began to fall. At the end of nine days there was no pyrexia, and after twenty-one days the treatment was discontinued, the patient being well. There was no subsequent return of symptoms.

Results as brilliant as this compelled a universal trial, and at the present time there is no doubt but that the creosote inhalations should be the routine treatment for every case of bronchiectasis. Unfortunately, there are a few cases that do not improve as much as is desired when so treated, and for these the other methods that have been described must be tried.

Necessary adjuncts to all these methods of treatment are the mechanical hygiene of respiration and climatic influence. Certain dry and stimulating climates have been found to greatly benefit the catarrh and the unhealthy mucous membrane.

Such are to be found nearest to this country along the Mediterranean coasts, and further afield in South Africa, California, and in some of the West Indian Islands.

But as the home treatment is now so much more efficacious than formerly, there is not the same need to rely on these especial sites, and many patients are sufficiently benefited by residence at one of our home resorts. In some instances the dry, cold atmosphere of the Alps is to be recommended in the winter months.

Hygienic measures ought not to be neglected, and the convalescent should continually practise inspiratory exercises and undergo a course of massage and passive movements applied to the abdominal and thoracic muscles. Such exercise will tend to promote the contraction of the sacculations and the general improvement of the respiratory functions.

In conclusion, it may be said that even the worst cases offer hope of improvement when systematically treated on the above lines, and, at all events, great relief can be given to the distressing symptoms; moreover, that in a minority of exceptional cases operation offers the greatest chance for recovery, and in a few well-chosen cases has produced excellent results.

THE PREVENTIVE TREATMENT OF NON-SPECIFIC DISEASES.

By P. LONDE, M.D.,
Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

WE must bear in mind that all parts of the organism are intimately connected for good or for evil in the living body. The sum of vital energy at the disposal of the individual is not unlimited, and there are moments in his existence when this has to be concentrated on one particular spot, as in combating infection or establishing a new function. In the young infant digestion is the principal function, and under ordinary circumstances matters go on smoothly until a demand is made on the fund of vital energy by some phase of evolution—teething, for instance. Provision must be made for this fresh demand, and if this be not done serious constitutional disturbance may accrue. Most of the accidents of dentition are due to over-alimentation, either comparative or absolute. The same remark applies to the establishment of puberty in the young girl. Here we must impose a large measure of repose, muscular, cerebral, and even digestive. At periods of rapid growth, it is true, a liberal supply of food is in a certain measure legitimate, but it will be all the more efficacious if associated with a reduced expenditure of energy. The menstrual function is throughout life a critical period. It comprises a salutary depletion, but it places the woman temporarily in a state of morbid imminence, and if the period be postponed by the necessity of concentrating the vital energy on a threatened point—lungs, liver, or what not—the woman will only recover complete equilibrium four weeks later, when the next period supervenes. Repose is therefore always indicated at the menstrual period.

At the menopause the suppression of a function entails the necessity for a modification of nutrition, and if the woman fails to conform to this requirement, nature will set up a supplementary emunctory, such as rheumatism, or bronchitis, or interstitial nephritis, or she may become a chronic dyspeptic.

The conclusion to be drawn from the study of the state of morbid imminence (see "Predisposition to Disease," MEDICAL PRESS AND CIRCULAR, October 10th, 1906, p. 385) is that all non-specific diseases are fundamentally identical—*i.e.*, they owe their existence to some change in the abdominal functions. In the complex human organism this change may be primary or secondary to a shortcoming on the part of the nervous system. It follows that a mild acute disease is often a fortunate circumstance, provided it be completely recovered from. It constrains its victims to repose and a healthful regimen, which arrest the morbid process, as is seen in the longevity of persons subject to migraine. Conversely it is by no means uncommon to see patients affected with chronic affections, and suitably treated, escape serious acute diseases, thanks to the rest and regimen which they are constrained to adopt. Most non-specific maladies can be avoided by timely recourse to rest and dieting. These two must always be associated, because rest facilitates digestion. The practice of resting after a meal which we inculcate on our dyspeptic patients is of unquestionable value. When we rest the voluntary centres, the sympathetic system can dispose of a comparatively larger amount of nervous energy for functional purposes. On the other hand, we cannot subject a patient or a person threatened with disease to a reduction of diet unless at the same time we insist upon repose—in other words, he must economise his strength.

The repose must be double in that it must ensure rest for the diseased organ, as well as of the whole organism, in order to liberate as much nervous energy as possible to fight the common enemy. Local affections tend to become general or to get worse if our energies are expended externally. Thus comparative repose should be insisted upon even in such affections as whitlow, zona, or even slight attacks of bronchitis, under penalty of the risk of aggravation or complications. For the principles that govern the preventive treatment of non-specific diseases are the same that must be applied when we desire to avert complications. It is good practice to be severe at the onset of even the most trivial maladies, and a rigid dietetic treatment is the best means at our disposal to curtail the duration of the attack.

The regimen must be a restricted or lessened one. It is always desirable to throw the least possible burden on digestion at the onset of an infection, whether grave or slight. In short but acute maladies, such as pneumonia, though it may be well to keep up the patient's strength by liquids, it is wrong to attempt feeding, properly so-called.

Absolute deprivation of food, and even liquids, is necessary in acute affections of the digestive tract, infantile enteritis, appendicitis hepatic colic, etc. Protracted liquid diet entails recourse to injections of serum, but the diet is itself an excellent preventive means. The child will never have grave enteritis or broncho-pneumonia or articular rheumatism if the patient has been subjected early enough and long enough to repose and diet. In every case the treatment should be strictly applied from the onset. Moreover, to avert recurrence, it is well to enrich the diet very gradually. The gradation of diet is the same in all diseases; at first diluted milk, or milk and egg; then pure milk and soups; then semi-solid foods, creams, purées, and lightly-boiled eggs. On the whole, abstinence from salt is a good thing in acute diseases. The food should be given in small quantities, frequently repeated.

These simple principles of hygiene are, unfortunately, unknown to many mothers of families and nurses; yet it is in early childhood that their efficacy is most clearly demonstrated, and it is at this age that negligence in this respect has the most disastrous consequences. In the newly-born, in a state of morbid imminence, rest is inadequate and illusory. The only prophylactic means at our disposal is functional rest. We cannot too strongly proclaim that the most important factor in determining the present high rate of mortality among the very young is, along with the too early administration of solid food, giving too much food.

It may safely be asserted that the majority of text-books advise far too large doses for the artificial feeding of infants. We do not recognise what a small quantity of cow's milk suffices to nourish an infant provided it be diluted with boiled sweetened water. Many infants twelve months of age do better on a pint and a half of milk diluted with half a pint of sweetened water than on a quart of pure milk. Between six and nine months a pint of milk is usually sufficient, provided it be diluted with a third of its volume of water. Between the third and fifth months the milk should be diluted with half its bulk of water, and given in fractional doses of one half to one pint. Infants under two months should not exceed half a pint, and the milk should be diluted with more than its volume of water—indeed, to begin with, twice its volume. These are merely general indications, for in every case we must be guided by the weight chart and the appearance of the stools. It is undesirable that a child should grow too quickly or get too big for its age.

The daily allowance of milk may be increased by about a teaspoonful every second day, so that by the end of the first year we shall have reached close upon two pints. For children over a year two pints is a maximum, and is not necessarily the proper quantity. The great point to be insisted upon is that when a child seems to be hungry, when it coughs, whenever the stools have too pronounced an odour, whenever it is in the least indisposed in any way, the fault lies in the direction of over-feeding. We must go back on our steps and very gradually re-increase the allowance. Even if over-feeding be not at fault, it behoves us, in presence of dentition troubles, to put the child on half rations. The treatment of the morbid state is the same as that of morbid imminence, and we must always commence by rest and diet.

In adolescents the treatment of the state of morbid imminence is somewhat different. Here muscular and cerebral repose is the fundamental requirement. Diet is only of use in so far as it is associated with rest. The regimen must be curtailed to begin with, then slowly augmented. Super-alimentation is only justifiable in growing lads on condition that it is preceded by a period of rest. We too often overlook the fact that it is contrary to common-sense to overfeed a patient or a threatened subject without insisting upon, at any rate, comparative repose. Too zealous and too hasty overfeeding is badly borne by many of these subjects.

The same remark applies to adults. Although we have to allow for the wear and tear of the struggle for life, we shall be doing good service to our patients if we insist upon an adequate cessation of professional work whenever the general health is below par.

At the change of life, and in old age, moderation becomes all the more necessary, since the expenditure of energy is reduced. Regimen, then, is here the essential feature. I have known old people, and even adults, who make a practice of putting themselves on half-rations, and remaining a day in bed once a fortnight.

The progress of surgery, on the one hand, and of pharmacology on the other, must not make us forget that it is always easier to prevent than to cure. A certain proportion of persons operated upon for appendicitis and gynæcological diseases derive much more benefit from the repose imposed by the intervention than from the operation itself when the latter was not very urgently indicated. A great many medicinal treatments are useless, and even injurious, if we lose sight of the fundamental element of the treatment—repose and rest. Medicine has everything to gain by getting rid of illusory and doubtful or ephemeral medications.

Lastly, when we are confronted with a disease of comparative specificity like tuberculosis, the safeguarding and utilisation of vital energy, along with reduction of digestive auto-intoxication, remains our sheet-anchor, hyper-alimentation only coming later.

Sir John Batty Tuke, recently giving evidence before the Royal Commission on the Care and Control of the Feeble-minded, at Westminster, advocated the division of England and Wales into five districts, in each of which there should be two resident Lunacy Commissioners instead of, as at present, the Commissioners all living in London. He compared the state of affairs in Scotland with that in England. In England three medical Commissioners supervised 121,979 patients, whereas in Scotland four medical Commissioners supervised 14,500. He drew attention to the simplicity of the Scottish system in lunacy administration and to the unnecessary amount of inspection of private asylums in England.

It is expected that the report of the Royal Commission on Vivisection is not likely to be presented to the King for at least a year. Meanwhile, it is announced that evidence will be published monthly.

THE TREATMENT OF SYPHILIS BY THE INTRA-MUSCULAR INJECTION METHOD: 100 CASES. (a)

By S. T. BEGGS, M.B., B.Ch.,

Gentlemen,—Having completed the treatment of 100 cases of syphilis by this method, I venture to place before you the following remarks:—

The treatment of syphilis by intra-muscular injections of mercury has been brought into prominence of recent years by Lieut.-Colonel Lambkin, R.A.M.C., and this method has been found to be well adapted for the treatment of syphilis in the Service, in which it is being used generally and is becoming more and more popular as a most suitable method of treatment.

The advantages claimed for the method are:—(1) The dose is definite; (2) fewer attendances are required; (3) it is a cleanly method; (4) professional secrecy is insured; (5) the action of the drug is more rapid; (6) less time is required in hospital; (7) the patient is able to attend to his daily duties during treatment.

The injection method is specially indicated (1) when rapid therapeutic effect is desired; (2) in syphilis of the central nervous system; (3) in hot climates where the gastro-intestinal system is more liable to be upset.

It is contra-indicated (1) in the case of patients who are about to travel and who cannot be seen at least once a week; (2) in very sensitive patients; (3) in patients suffering from marked cachexia.

The dangers and disadvantages brought forward against this method of treatment would appear to be exaggerated, and are avoidable by proper attention to detail of technique:—These are (1) embolus; (2) mercurial intoxication; (3) mercurial stasis, (4) sepsis, sloughing and inflammatory reaction. Thus Lieut.-Col. Lambkin reports the treatment of over 3,000 cases with 60,000 injections without a single complication. I have seen a case of inflammatory reaction, but this was in an alcoholic patient; also cases in which nodes were formed, but these caused no inconvenience to the patient. This latter condition indicates the non-absorption of the Hg. and is thus a guide to the diminution of the dose and the withholding of further injections until the mercury becomes absorbed.

The unabsorbed Hg. at the seat of the injection can be revealed by means of the X-rays. Therefore, before re-injecting a patient, it is always necessary to examine for nodosities.

The injections may be carried out by means of (1) the soluble salts; (2) the insoluble.

The advantages claimed for the soluble preparations are (1) their rapid effect; (2) the ease with which they can be given.

They are specially indicated in (1) tubercular cases; (2) in cases with extensive caries; (3) in cases in which the liver or kidneys are not acting well; (4) in young children; (5) in eye cases; (6) in the debilitated.

The disadvantages against their use are (1) the frequency of administration; (2) the effect is not so lasting as in the case of the insoluble preparations. This is due to the fact that much less Hg. is injected per dose than when the insoluble preparations are used.

(a) Read at meeting of the Ulster Branch, British Medical Association, Nov. 3rd, 1906.

The advantages claimed for the insoluble preparations are (1) fewer injections are required; (2) the effect is more lasting.

They are contra-indicated in (1) liver and kidney disease; (2) in the old; (3) in caries of the teeth; (4) in cachectic patients.

The disadvantages put forward need not arise if proper precautions are taken.

The dosage in intra-muscular injections varies with (1) the preparation used; (2) the weight of the patient; (3) the resistance of the patient; (4) the object aimed at.

Bing advocates beginning with a small dose first in order to test the patient's susceptibility.

The frequency of the injections will depend on whether the soluble or insoluble preparations are used. With the soluble salts daily injections may be required; with the insoluble preparations the injection is given every seventh or fourteenth day only.

The course consists of 20 to 30 injections of the soluble salts, and from 10 to 20 injections when the insoluble preparations are used.

The comparative values of the different methods of treatment are of interest: *e.g.*, one injection of mercurial cream (1½ gr. Hg.) is said to equal three injections of the soluble salt (containing ½ gr. Hg. in each injection) = seven inunctions of mercurial ointment (using 20 gr. Hg. daily) = 21 pills (containing 2 gr. Hyd. c. cret. t. in. die.).

The preparation most extensively used is Lambkin's:—

℞ Hydrargyri .. .. 1 ounce.
Adeps lanæ .. .. .. 4 ounces
Paraffini liquidi (carbol 2%) ad 10 ounces.

(Hg. and fat by weight, paraffin by volume). 10 min. = 1 gr. of Hg. pro. dos.

Special care is required in the dispensing of this preparation so that the Hg. is thoroughly mixed with the excipients. The Hg. and lanoline require to be triturated for two hours and then paraffin liq. carbol. is added and the whole well mixed. It is stocked in a wide-mouthed glass-stoppered bottle with rounded angles.

Many other preparations of the soluble and insoluble salts are used by different authorities. Of the insoluble salts calomel is the most effective, but it is painful.

PROCEDURE.

I.—Before injecting (1) the patient's weight must be noted; (2) the urine examined; (3) the liver examined and any recent intestinal trouble enquired into; (4) teeth and gums are examined, and any badly decayed teeth extracted.

II.—The site for injection must be carefully selected. The buttock is the most suitable, and here different points are advocated:—(1) The retro-trochanteric region (Smirnoff); (2) a point obtained by drawing a line horizontally two fingers' breadth above great trochanter with a line drawn vertically parallel to and two fingers' breadth outside inter-gluteal fold (Galliot).; (3) upper third of buttock (Fournier); (4) middle of line drawn from top of inter-gluteal fold to anterior superior iliac spine (Barthelemy).

The dangerous area, as defined by Möller lies between the posterior superior iliac spine and the great tuberosity of the ischium.

III.—The injections must be carried out with aseptic precautions; the needle used is rather longer than the ordinary hypodermic needle, and is made of platino-iridium. An all-glass syringe is used. The needle and syringe are sterilised and washed in boiling oil before each injection. The skin at the site of injection is rendered sterile by the ordinary surgical methods. The mercurial cream is kept at a temperature of 80° F. by the bottle being set in water maintained at that temperature, a thermometer being used as indicator. Care must be taken that the temperature of the water is not raised to boiling point, otherwise the Hg. will become separated and be deposited. Before the cream is taken up into the syringe, it is well stirred with an aseptic glass rod.

The injection is made in two stages:—(1) the needle is sharply thrust into the muscle vertically; (2) the syringe is then detached. This precaution will insure that a blood-vessel is not injured, and thus any danger of embolism avoided. Should any blood escape the needle is withdrawn and another site selected. After injection the skin is dried with an aseptic swab and the puncture touched with collodion. No pain is felt if the needle is thrust in sharply, and there are no after-effects beyond a feeling of slight stiffness in some cases where there has been much muscular exertion.

The next injection will not be given for a week or a fortnight. The interval between each injection and the dose will be determined by the nature of the case; no hard and fast rules should be laid down, each case being dealt with independently on its own merits.

Before re-injecting, unabsorbed mercury should be examined for; which will be indicated by the formation of a nodule at the site of injection.

During a course of intra-muscular mercurial treatment the ordinary precautions will be taken as to the condition of the teeth and gums, antiseptic and astringent mouth-washes being used, together with the toothbrush; the general health and dieting should be attended to, together with a judicious restriction in the use of tobacco and alcohol.

Bing gives the following as the signs that Hg. is agreeing with the patient:—(1) there is an increase in the amount of urea excreted; (2) the percentage of hæmoglobin is raised; (3) the body weight increases. The presence of albumen in the urine, or a decrease in the body weight will be indications for a temporary suspension of the injections. The length of a course of treatment will vary with the nature of the case, each case being managed independently. A general softening and a disappearance of the indurated lymphatic glands probably give the best guide. It is a safe rule to keep the patient under observation for at least two years.

THE OUT-PATIENTS' ROOM.

KING'S COLLEGE HOSPITAL.

Disorganisation of Joints.

By PEYTON BEALE, F.R.C.S.

A WOMAN, æt. about 35, came to the Out-patient Department complaining of intense pains in the right wrist, left elbow, and left knee. All these three joints were considerably enlarged and contained fluid; they were very tender to the touch and also when the least movement, passive or active, was attempted. In the case of the wrist and the elbow, very distinct bony crepitus was noticeable on slight movement in certain directions, and there was no doubt that in the case of the wrist there was disease affecting the intercarpal

joint and that it was practically disorganised. The elbow and the knee had not advanced to such a condition, but it was quite clear that they were affected in the same manner. The process was a slow one, for it had been going on for a year and a half and upon inquiry it was found that the patient had then suffered from a severe attack of acute rheumatism. The excessive pain in the joints had not been present continuously, but came on in exacerbations every few weeks.

A woman, æt. about 25, presented herself complaining of pain in the right knee; she could walk only with great difficulty on account of the pain, and also on account of the knee being kept slightly flexed. The skin around the joint was œdematous and on making firm pressure the patient experienced great pain. Normal movement was very limited, and was attended with crepitus or grating at times. There was a considerable amount of abnormal movement present, namely, lateral movement. Had it not been for the œdema, the severe pain and the semi-flexed position, the joint resembled a Charcot's joint with loose bone within it. On careful inquiry the symptoms were found to date from convalescence after typhoid fever about nine months previously.

Mr. Beale said that these two patients were suffering from a kind of more or less chronic pyæmia with acute exacerbations; the condition occurred as a sequela of acute specific fevers, such as scarlet fever, typhoid, rheumatic fever, and also after acute pneumonia. They were not at all like the pyæmic condition met with after gonorrhœa, for in the latter cases one could almost tell by the patient's aspect (sallow, earthy complexion), and the fact that there was a good deal of pain which moved from one joint to another. He said the cases above described were not common, but when they were met with they were seldom recognised; and were generally regarded as tuberculous. One of the characteristics of them, however, was that the condition was essentially a chronic one, associated with exacerbations, and during one of the latter it was not unusual for an abscess to form and to burst discharging thin, flaky pus with pieces of cartilage and even bone. He was in the habit of treating these joints by the application of a strong counter-irritant, together with pressure. In the first case of the kind he saw, some years ago, he advised amputation on general principles, for the wrist-joint was completely disorganised, the carpal bones were loose, and pus had been obtained with an exploring needle, but as the patient absolutely refused to lose her hand, he was obliged to treat it otherwise, and was considerably surprised to find that counter-irritation, in the form of red iodide of mercury ointment, carried to the extent of destroying the epidermis, and followed by firm pressure, not only markedly relieved the pain, but also resulted in the complete absorption of all the fluid and the consolidation of the carpal bones. He said that this condition did not seem to occur in the wrist (radio-carpal) joint, but in the inter-carpal joint; at any rate, so far he had not come across one affecting the wrist-joint proper. It was of course necessary to adopt constitutional treatment as well in the shape of tonics and plenty of fresh air.

OPERATING THEATRES.

ITALIAN HOSPITAL.

Paget's Disease of the Nipple.—Mr. Lenthal Cheatle operated on a woman, æt. 56, who had been admitted suffering from a red scaling surface over the position where the nipple had previously existed, the nipple having disappeared in the course of the disease. The red surface was dry; the base of the sore revealed a card-like infiltration; the patch was as large as a florin. The nipple of the other breast was normal; no glands could be felt in the axilla of the side of the disease. Scales had been scraped off, dried on a slide, mounted in a 40 per cent. potash solution, and examined immediately with a six-inch objective. There were seen imbedded in the scale, or floating in the serous discharge, bodies with a well-defined double outline and a central nucleus. On these physical signs, Paget's disease of the nipple was diagnosed. The trouble had a history of six months. Mr. Cheatle excised the whole of the breast, the fascia covering the pectoralis major, and the glands in the axilla. Great care was taken to prevent infection of the newly-formed wound during the removal of the disease by covering the raw-looking and septic surface with a small collodion and gauze dressing, and the incisions were so made as to render impossible any flow of blood over this dressing into the newly-formed wound. The edges were brought together by undercutting the flaps. Mr. Cheatle said that opinions seemed to be divided as to what Paget's disease of the nipple really was. Sir James Paget, who first described the lesion, so far as he (Mr. Cheatle) could see, made no definite statement beyond saying that within a couple of years or so the disease generally was associated with malignant disease of the breast. At the present time two schools of thought existed; one say that it is a condition which generally ends in malignant disease, and describe it under the vague term of malignant dermatitis, which means practically nothing definite; the other school regard the disease as malignant from the beginning; he himself agreed with the latter view. Some people, he said, in the treatment of this disease begin by the application of certain lotions with a view to its cure, and tell us that in some cases they are successful, but there can be no doubt that certain forms of Paget's disease are occasionally cured by the external application of certain remedies, but it is quite possible that in some of these cures the disease was not Paget's disease at all; in any case, it is impossible to tell how deep the disease has spread into the ducts unless microscopical sections are cut of the breast tissue underlying the nipple; it is therefore obviously wrong treatment to treat this disease by external applications when one is completely ignorant in any given case as to what depth the disease really has extended; the only safe course to pursue in every case is to excise the breast and glands, as had just been done. The disease is diagnosed from eczematous eruptions by the dry surface and card-like infiltration. In syphilitic lesions of the nipple the induration is much thicker and feels like a small lump.

Large sections of the whole breast were cut, and showed that the disease had spread deeply into the ducts—even as far as the alveoli in some parts. This proved that although the disease occupied a small area on the surface, it had spread too deeply to be influenced by any external remedy.

TRANSACTIONS OF SOCIETIES.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, December 14th, 1906,

The President, Mr. Clutton, being in the chair.

Mr. G. A. Moynihan read a paper on

THE MIMICRY OF MALIGNANT DISEASE OF THE LARGE INTESTINE.

He gave detailed records of six cases upon which he had operated within the last few years. In all of these a diagnosis of malignant disease of the large intestine had been made at the time of operation or before, yet subsequent examination of the specimens

or the after-history of the cases showed that the diagnosis had been incorrect. In the first case, a woman, æt. 29, was operated upon for intestinal obstruction, due to a growth which blocked the rectum. Left inguinal colotomy was performed, and six weeks later the whole of the rectum and the sigmoid flexure below the colotomy opening were removed by the abdomino-perinæal route. An examination of the specimen, which was shown, revealed no evidence of malignant disease. The rectal walls were considerably thickened and stenosed. The mucous surface showed heaped-up irregular masses of soft growth, here and there ulcerated to a degree which resulted in festoons of mucous membrane being left, attached at each end, free in the middle. There were numerous deep pockets in the thick wall of the gut, due to ulceration. There was no evidence of tubercle or syphilis.

In Case 2, a woman, æt. 58, there was a large tumour of the sigmoid flexure, with perforation, and a localised abscess. The patient was operated upon for acute obstruction in 1904. The tumour has disappeared entirely, and the patient is quite well. The case was considered to be one of subacute perforation of a false diverticulum of the sigmoid.

Case 3, in a woman, æt. 50, was an example of inflammatory tumour, due to pericolitis transversa affecting the left end of the transverse colon. Colectomy was performed for a tumour as large as a cocoanut. Subsequent examination showed only an immense thickening of the outer coats of the intestine; the mucous surface was intact.

Case 4, in a woman æt. 41, was similar to Case 1.

Case 5 occurred in a man æt. 52 who was operated upon for symptoms of duodenal ulcer, and who had suffered for some months from intermittent attacks of acute intestinal obstruction. A large duodenal ulcer was found. When the large intestine, a growth in which had been suspected, was examined, a tumour as large as the fist was felt in the sigmoid flexure. This was removed and axial anastomosis performed. The tumour on section showed a large number of false diverticula, one of which had perforated. The walls of the gut were 1¼in. thick. No evidence of malignancy could be discovered.

Case 6, in a woman æt. 62, was one of inflammatory tumour of the splenic flexure, which disappeared entirely after a shortcircuiting operation.

In drawing attention to these cases, Mr. Moynihan remarked that the mimicry of malignant disease in the cæcum and ascending colon by a hyperplastic tuberculous process was well known. He had performed colectomy on two such cases in the belief that he was dealing with cancer. It was, however, not so generally known that inflammatory tumours presenting all the clinical appearances of cancer existed in all parts of the large intestine. Many of these were possibly due to the presence of false diverticula, the origin and complications of which were discussed.

The PRESIDENT alluded to the importance of Mr. Moynihan's paper. He drew an analogy between the cases just described and those of gastric tumours, which were thought to be cases of cancer, but which disappeared after gastroenterostomy. As to the rectal cases that were usually assumed to be due to a gummatous interstitial myositis, he was extremely sceptical about the syphilitic nature of many of them.

Dr. BROOK (Lincoln) related a case of a patient, æt. 65, who had been operated on for acute intestinal obstruction. A fixed tumour of the cæcum had been found, and shortcircuiting performed. Eighteen months after the man was perfectly well, and there were no signs of any tumour.

Mr. W. G. SPENCER had operated on a similar case, and seven years afterwards the intestine proved at autopsy to be quite normal. He suggested that many of the cases of so-called malignant disease that recovered after exploratory operation alone must be of this nature.

Mr. MOYNIHAN, in reply, said that though at first he had thought that one of the cases was syphilitic he had failed to find any evidence at all confirmatory of this. He considered that differences could be established between the appearances of the non-syphilitic and true syphilitic cases. In the literature he had found notes of forty cases of false diverticula of the large intestine. He had seen, however, in museums specimens of a number equal to this, but wrongly described as malignant disease.

Mr. JAMES BERRY read an account of

A CASE OF TRAUMATIC HERNIA THROUGH THE DIAPHRAGM.

A railway man, æt. 19, was admitted to the Royal Free Hospital on November 11th, 1898, having been squeezed between buffers shortly before admission.

He was greatly collapsed, and there were physical signs of rupture of the left lung, with much effusion of blood and air into the left pleura. It was believed from the nature of the injury that the diaphragm also had been injured. During the next three days he remained in the same extremely bad condition. The heart became more and more displaced to the right, and the pneumo-hæmothorax increased. He vomited occasionally.

The circumference of the abdomen measured 28½ on admission, but gradually diminished to 24½ inches. On the evening of November 15th the vomiting became much more frequent and violent; the vomit evidently contained much altered blood. As the symptoms pointed to strangulation, it was decided that, desperate as was the man's condition, an attempt ought to be made to reduce the strangulation. The abdomen was opened. A large rent in the left posterior part of the diaphragm was discovered. Through this most of the stomach and transverse colon, all the great omentum, one half of the spleen (which had been cut in two), and the upper end of the left kidney had passed into the thorax.

The herniated viscera were grasped moderately firmly by the edges of the opening in the diaphragm, and were drawn back into the abdomen with some little difficulty. The rent in the abdomen was closed, partly with sutures and partly by fixing the left lobe of the liver so as to block up the posterior part of the opening, which could not be sutured. The operation lasted half an hour, and the patient died almost immediately afterwards.

The difficulties of diagnosis in this case were considerable, owing to the similarity of the physical signs of pneumo-thorax and hernia of the stomach, and to the fact that both these conditions co-existed.

The diminution in the circumference of the abdomen and the subsequent vomiting of coffee-ground material were the main points upon which the diagnosis of hernia of the stomach was made.

Mr. J. PAUL ROUGHTON read an account of

A CASE OF RUPTURE OF THE DIAPHRAGM.

The patient, a shunter, æt 49, was admitted into hospital, October 27th, having been squeezed between buffers. Examination revealed no lesion of importance, but patient complained of pain in the back and precordia.

On October 28th the severe pain continued; it was increased on swallowing. The right hypochondrium was slightly retracted. The movement of the chest on the left side was impaired; the cardiac dulness was absent, and left side of the chest hyperresonant.

The diagnosis was confirmed upon opening abdomen. The patient's grave condition only allowed of the stomach, which had risen high into the chest, being pulled down, and the wound stitched. There was passage of blood from chest into abdomen upon traction of stomach. The patient died October 29th. 1 a.m.

Post-mortem.—The left lung was completely collapsed. The chest contained about three-quarters of the stomach; the spleen also was in chest. The diaphragm torn away from its attachment between the ensiform cartilage and ninth rib, thus forming simply a shelf between the chest and abdomen. There was a tear in the spleen, probably the source of the blood, which flowed from the chest into the abdomen. The points to be specially noted are (1) the unequivocal nature of the signs of rupture; (2) the delay of serious symptoms which made the case an apparently favourable one for operation.

The President commented on the great interest of the cases.

Mr. W. G. Spencer congratulated the authors as aiding in the introduction of operative measures in these cases. He alluded to the analogy from a surgical point of view between them and the congenital cases.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

President: H. R. Swanzy, President R.C.S.I. Sectional Secretary: Edward H. Taylor, M.D., F.R.C.S.I.

Meeting held Friday, November 30th, 1906.
The President in the Chair.

SPHINCTERIC CONTROL OF THE BLADDER IN RELATION TO PROSTATECTOMY.

Mr. Arthur Ball read a paper on the above subject. Having pointed out that it had generally been accepted that in man the important muscle was the compressor urethræ, he described a case of perineal prostatectomy in which there had been almost perfect control through the perineal fistula after the drainage tube had been removed five days after the operation. In this case control must have taken place by means of the internal sphincter vesicæ. As the result of this observation, Mr. Ball had carried out experiments on dogs, having ascertained the anatomical similarity was greater in the dog than other animals, including the commoner forms of monkeys. These experiments, which were described in detail, proved that the important sphincter muscle in the dog was the internal sphincter vesicæ. Incidentally, he pointed out that the prostate might enlarge to an enormous size in the dog without producing any symptoms. In conclusion, he stated that in order to prove absolutely that in man the internal sphincter is the important muscle, it will be necessary to obtain observations on all cases of surgical interference with this region, particularly in young patients that have not reached the complication of an enlarged prostate, and that it seemed quite incorrect to argue from operations on patients with enlarged prostates that the chief sphincter of the bladder normally lies in the membranous urethra.

Mr. T. E. Gordon considered the communication one of the most important which had been laid before the Academy for some time. The experiments appeared to be conclusive as far as they went, and as far as it was possible to draw inferences with regard to human physiology from the anatomy and physiology of the dog.

Mr. Jameson Johnston said it had been difficult for him to account for the complete control after suprapubic prostatectomy. He could not conceive that the internal sphincter could exist after the amount of manipulation which it had to undergo, and he thought the amount of damage done to the bladder wall would prevent the internal sphincter from acting again.

Mr. Gunn said that in cases where the prostate had been removed by the suprapubic method, and where he thought the internal sphincter was either destroyed or taken away, good control had been got. He believed that the compressor urthræ muscle was the most important to leave behind when interfering with the bladder.

LIMITS OF ABDOMINAL OPERATIONS.

Mr. T. E. Gordon read a paper on the above subject, and, in the course of his remarks, discussed the indications for fixation of a movable kidney. He drew a distinction between those cases in which the symptoms were clearly referable to the kidney and those which were only "associated." Amongst the latter he specially referred to vomiting and other evidences of gastric disturbance. Whilst operation seemed justified in the first class, in the second it was likely to be disappointing in its result. He held that the vomiting, though, no doubt, occasionally a nervous reflex phenomenon, was usually caused by a gastroptosis, and could not therefore be benefited by a nephopexy. He specially insisted on the folly of operating to cure a general neurotic state. Mr. Gordon considered that the proper limits of operation had been exceeded in cases of movable kidney, but he did not think that this had been the case in the treatment of appendicitis. He thought that one attack of appendicitis was sufficient to justify operation, but this attack must have been unequivocal. The difficulty here lay in diagnosis, and he gave instances of such difficulty which he had met with in practice, and he said that the difficulties arose from the remarkable variability of the disease. Thus one might see appendicitis without fever, and sometimes without distinct tenderness in the right iliac fossa. Again, the position of the tumour varied, and he had met with a case of undescended cæcum where the appendix was coiled up close to the gall bladder and pylorus. He also referred to the association of appendix pain with pneumonia. In conclusion, the limits of operation in the surgery of the stomach were briefly alluded to, particularly with reference to gastro-enterostomy as a treatment for gastroptosis. Here again a decided neurotic element was a bar to operation.

Mr. W. Taylor said it was not always easy to be certain that symptoms were distinctly referable to movable kidney. In his experience a larger proportion of cases of stomach trouble than Mr. Gordon appeared to concede were due to movable kidney. The speaker instanced several cases bearing on the point, as also on the difficulty of diagnosis in appendicitis.

Mr. Jameson Johnston agreed that only cases in which the symptoms were directly traceable to misplaced kidney should be subjected to operation. He had never seen two cases of appendicitis exactly alike, and he would be glad to have information as to the exact indications for operation.

Mr. Gunn thought that in almost every case where they got a tumour in the appendix region pus was present. He referred to kinking of the ureter as a test.

Mr. Blayney said that Mr. Gordon's statement that it was inadvisable to operate in acute appendicitis while inflammation was present should not be allowed to pass without some qualification. It was, of course, advisable not to operate if it could be ascertained certainly that the patient would recover. But there was no definite way of doing so, and he believed that if patients were all operated on in the first 24 hours in acute appendicitis, there would be less harm done than by adopting the waiting policy.

Messrs. Ball, Stokes, and Kennedy also spoke.

HARVEIAN SOCIETY.

Meeting held Thursday, December 6th, 1906.

Dr. W. F. Cock, President, in the Chair.

Dr. Robert Boxall opened a discussion on

THE MODERN METHODS OF DEALING WITH ORDINARY CASES OF LABOUR.

He referred to the mortality in lying-in hospitals 30 years ago, which then amounted to 14 per cent. This had greatly decreased of late years, but the mortality in cases not treated in hospital was still very high. He thought that the main cause of the high mortality was septic absorption from laceration of the parts or use of instruments, and the imperfect methods of employing antiseptics by those not specially trained in their use. It was not merely the use of antiseptics, but the proper methods of employing them, which had led to such a great improvement in the statistics in lying-in hospitals. Training in the use of antiseptics was as important for students as it was for nurses and midwives, and neglect of proper training of the former might be accountable for the high mortality of private cases as compared with that of lying-in hospitals.

Dr. Horrocks referred to the time, 100 years ago, when pyrexia, after delivery, was the rule, and lying-in hospitals were regarded as a hot-bed of infection. The proper use of antiseptics subsequently effected a great change and improvement in statistics. Syringing was

introduced, and freely used, but discontinued when it was seen that the hand of the accoucheur most commonly introduced the septic material. Attention was then paid to rendering the hand aseptic. He considered that nature effected delivery by herself better than any artificial aids employed to assist her. He did not approve of the administration of chloroform or the use of forceps unless absolutely unavoidable. Even if forceps were used with strict antiseptic precautions, laceration and tears often ensued, and gave rise to troubles later on. At Guy's Hospital forceps were only applied in 4 or 5 per cent. of cases, and the mortality was very low. He did not consider that gonorrhœa was a cause of puerperal fever, though it might give rise to ophthalmic neonatorum. He deprecated the routine dropping of irritating lotions into the eyes of new-born children, which might, in the absence of gonorrhœa, give rise to severe ophthalmia.

Dr. HUBERT PHILLIPS said that the mortality in his cases of midwifery was only 1 per cent. He usually examined more than once, always using strict antiseptic precautions. He left delivery to nature as far as possible. He only douched after instrumental delivery, and then only once, as a rule.

Dr. ADAMS did not approve of the administration of chloroform, as he considered it had a marked effect in diminishing the pains, and often necessitated the use of instruments.

Dr. BLUETT considered that laceration of the perinæum might, with proper care, be prevented in the majority of cases, even in primiparæ and when forceps were employed.

Dr. PAYNE raised the question as to whether the routine use of ergot was advisable.

Dr. HANDFIELD-JONES said that a distinction must be drawn between hospital and private cases. For instance, chloroform was seldom necessary in the former, but was often essential and beneficial in the latter. If used in moderation, it did not interfere with labour in the first and second stages, and in the third stage it might prevent rupture of the perinæum. For hospital cases ergot was seldom necessary, but in private cases its use was frequently called for. He did not agree with Dr. Boxall that the mortality in cases treated out of hospital was due to deficient training of students in the use of antiseptics. The statistics of maternity cases treated at their own homes by students at the large hospitals was very low. The high mortality was due rather to the insanitary surroundings of poorer patients, and, above all, to examination of the patients by unskilled, "so-called" midwives, who infected cases before they were seen at all by a doctor.

Dr. LEWERS maintained that it was advisable, as far as possible, to make out the position of the child by external examination only, and dispense with vaginal examination in the majority of cases, as absolute disinfection of the hands was scarcely possible, and vaginal examination was therefore a source of danger. If this was necessary, sterilised rubber gloves should be worn. Some cases of sepsis occurred in spite of all precautions, probably from the introduction of pathogenic organisms from the vulva, which might be carried in by the finger or by douching.

The PRESIDENT held that a large proportion of cases of septic trouble were due to infection by an ignorant midwife. He would say, "Mark well your hands; therein the danger lies."

GLASGOW EASTERN MEDICAL SOCIETY.

MEETING HELD DECEMBER 5TH, 1906.

The President, Mr. THOMAS BARRAS, in the Chair.

Dr. JOHN PATRICK showed a case of

MALOCCLUSION OF THE JAWS,

which had been rectified by Mr. J. J. Manson, L.D.S., Glasgow. The patient was shown last year to the society, and at that time he could not bring his incisor teeth together, although the molars could be brought into apposition. He was partially starved owing to the difficulty created by imperfect mastication. Mr. Manson removed the posterior molars and fitted, in the mouth, a plate with artificial teeth. The result was very satisfactory, as the lad had gained in weight, and his facial expression was rendered comely. The case appeared to be congenital, as his father and two brothers had been similarly affected

Dr. SAMUEL CAPIE showed a case of "winged scapula," and a case of localised "œdema of the face." The former he considered was due to paralysis of the serratus magnus, from neuritis.

Dr. DAVID COUPER showed a case of extensive

CARBUNCLE

in the neck, in which he had operated with success. He said it was the largest one he had seen. It was at least 4 in. by 4 in. The patient was put under chloroform, the carbuncle incised, freely scraped and cauterised with pure carbolic acid. Healing was rapid, and a comparatively small scar left.

Dr. WILLIAM CHRISTIE related several cases, where he had incised carbuncles by free incisions with good results. In one case, where the patient had saccharine urine, he succumbed.

Dr. MACLACHLAN stated he had been in the habit of ordering wet boracic dressings, covered with oil silk to carbuncles, the dressings being renewed frequently. At the same time he put the patient on 2 grains of quinine every few hours. Under this treatment most cases of carbuncles gradually quieted down and dwindled, leaving a small indurated lump, which finally disappeared. If a carbuncle had burst it was desirable to remove the sloughing material with as little delay as possible. By using dressing forceps, sloughs could be twisted out, leaving a cavity which rapidly healed with iodoform dressings.

LIVERPOOL MEDICAL INSTITUTE.

MEETING HELD THURSDAY, DECEMBER 6TH, 1906.

The President, FRANK T. PAUL, F.R.C.S., in the Chair.

EXHIBITION OF CLINICAL CASES, ETC.

THE PRESIDENT showed a patient, 63 years of age, from whom he had partially removed an epitheliomatous cyst which had been growing for two years under the left sterno-mastoid muscle. The cyst contained a clear brown fluid and flocculi, and its walls resembled those of a dermoid cyst. There was too much surrounding infiltration to permit of the complete removal of the growth. The microscopical examination of the portion removed showed that it was a deep epithelioma.

Mr. DAMER HARRISSON, Mr. W. H. BROAD, and Mr. ALLAN PINDER also showed surgical cases, while the President and some other members exhibited their portable operating tables.

Among the medical cases were a rare case of myositis ossificans, shown by Dr. J. Hill Abram; a case of mitral stenosis, with no cardiac murmur, but with marked backward pressure in the veins, shown by Dr. T. R. Bradshaw; fibroid lungs, by Dr. R. J. M. Buchanan; aneurism of the aorta, innominate artery and right carotid, and a case of exophthalmic goitre, which was improving under the internal administration of rodagen, by Dr. A. G. Gullan.

An instructive series of skin cases were shown by Drs. F. H. Barendt, H. Leslie Roberts, and G. Stopford Taylor. Among Dr. Taylor's cases was one of Recklinghausen's disease, with elephantiasis of the left leg and fibroma of the palm. The patient was a woman æt. 44 years. The leg began to swell 23 years ago, and now measured 35 inches around the calf. The fibromata of the palm and trunk had begun 20 years ago. Dr. Taylor also showed a girl, 5 years of age, with urticaria pigmentosa, which began when the child was 9 months old.

A number of interesting eye cases were exhibited by Mr. T. H. Bickerton, Dr. K. Grossmann, and Mr. Charles G. Lee.

BRACHIAL PALSIES.

Dr. W. B. Warrington read a paper written jointly by himself and Mr. Robert Jones entitled "Observations on the Palsies of the Brachial Plexus, and Some Remarks on Recent Work on Treatment of the Lesions of Peripheral Nerves."

The paper was discussed by Mr. Damer Harrisson, Mr. G. G. Hamilton, Mr. R. W. Murray, and Prof. A. M. Paterson.

ULSTER MEDICAL SOCIETY.

Meeting held Thursday, December 13th.

The President, Dr. D. P. Gaussen, in the chair.

Dr. John Campbell read a paper on

THE USE OF RUBBER GLOVES IN MIDWIFERY PRACTICE.

He advocated their routine use, both on account of the additional safeguard to the patient and also on account of the ease they gave to the medical man's mind, for, if infection did occur, he felt that he had done all in his power to avoid it, and had taken every possible precaution; whereas, if gloves were not worn, he might feel that, if only they had been, infection might not have occurred. He gave some account of the very general use of gloves in some districts, and then described the way in which he used them, taking them to the house where they were to be used and boiling them there in an ordinary saucepan. The only objection to their use was that the patient or her friends might think one was afraid of soiling his hands, or feared infection for himself, but the public was intelligent in such matters, and soon appreciated the advantages obtained by their use.

The paper was discussed by the President and Dr. Kevin.

Dr. Campbell also showed (a) a hydatid mole; (b) two hundred and sixty-two gall-stones recently removed from a gall-bladder; (c) eight hundred and two gall-stones removed from a gall-bladder and cystic duct.

Drs. Darling and James Wilson read notes of "A Case of Cerebro-Spinal Meningitis, from the Lumbar Puncture Fluids of which a Pleomorphic Diplococcus was Isolated." Details of this case, which is of peculiar interest, will be published later. It was discussed by Professor Symmers, who congratulated the authors on a most successful piece of research work.

Drs. B. H. Steede (Rostrevor) and G. A. Hicks (Belfast) were elected Fellows of the Society, and Drs. John O'Doherty, P. T. Crymble, and W. Hill, all of Belfast, were elected members.

CORRESPONDENCE.

FRANCE.

Paris, Dec 16th, 1906.

CIRRHOSIS OF THE LIVER.

As soon as the disease is recognised, the patient should be enjoined the reclining position to facilitate the circulation of the liver. Absolute milk diet is one of the most important conditions of a cure. It should be continued until the complete disappearance of all the morbid symptoms, and for several months afterwards, before he is allowed to return to his ordinary régime.

From this régime, however, should be excluded all alcoholic liquors, condiments, acid fruits, pork, meat, fish, and shell-fish, fats, and "high" meat.

As to the medical treatment, Professor Robin gives a primary place to iodide of potassium, which he considers preferable to iodide of sodium, and might be prescribed with strychnine.

Iodide of potassium	dr. j.
Sulphate of strychnine	gr. ½.
Water	ozs. x.

A tablespoonful before the two principal repasts.

Strychnine acts on the nervous system, while the potassium stimulates the vessels.

To increase the biliary secretion, salicylate of soda constitutes the best cholagogue. However, it is not always tolerated, and might be replaced by benzoate of soda or phosphate of soda, to which is added small doses of jaborandi.

Benzoate of soda	gr. v.
Phosphate of soda...	gr. x.
Powdered jaborandi leaves	jj.

For one wafer. Two a day one hour before meals. To further increase the secretion, the wafer might be taken in an infusion of boldo (half a drachm for 6 ozs. of water).

Some authors have tried massage, but the experiments cannot as yet be said to be conclusive.

Each evening the patient should take a more or less drastic pill.

The above treatment may be applied to all cases of cirrhosis. However, complications may require something more.

In certain patients oliguria is frequent, and the best treatment in such cases is theobromine, associated with phosphate of soda.

Theobromine ... ... } Phosphate of soda ... ... }	aa gr. x.

For one wafer; three daily at one hour's interval between each.

In case of failure the following pills might be prescribed:—

Powdered squills ... ... } ,, digitalis ... .. } ,, scammonium ... ... }	aa gr. 1.

For 1 pill; 2 to 4 in the 24 hours, or

Acetate of potash ... ... } Nitrate of potash ... ... }	drs. ss.
Oxymel scillæ	oz. j.
Infusion of broom flowers	ozs. v.

A tablespoonful every hour.

Calomel is a good agent at times, and might be given in two-grain doses every four hours, but not more than eight grains should be given in the 24 hours.

If ascites is abundant and oliguria persists, the liquid should be tapped, and when the abdomen is evacuated the medical agents act with renewed activity.

The most unfortunate complication in cirrhosis of the liver is hæmorrhage; it constitutes frequently the initial symptom, and is sometimes extremely abundant. As soon as it presents a certain gravity the treatment of acute anæmia should be applied, absolute rest, repeated injections of serum, etc. In benign cases chloride of calcium should be prescribed.

Chloride of calcium	dr. j.
Syrup of opium	oz. j.
Water	ozs. v.

A tablespoonful every hour.

NOISES IN THE EAR.

Noises in the ear, independent of any local lesion, are best treated with bromide of sodium, at the dose of 30 or 40 grains, in a little water an hour before bedtime, or

Bromide of potassium	dr. j.
Bromide of sodium	dr. j.
Bromide of ammonia	dr. ss.

dissolved in a bottle of effervescing mineral water, of which one or two wineglasses may be taken before bedtime, and continued three weeks.

During this treatment, says Dr. Huchard, the patient should abstain from fatty or acid foods.

In numerous cases the following gives excellent results:—

Bromide of sodium	grs. 30.
Antipyrin	grs. 4.

To be taken before bed-time.

Where vertigo accompanies buzzing, quinine should be prescribed in two-grain doses, three times a day.

If the noises persist, a blister might be ordered behind the ear.

DR. DOYEN'S TREATMENT OF CANCER.

Dr. Doyen presented to his colleagues about fifteen patients treated by him for divers forms of cancer.

Certain patients considered incurable four years ago are to-day in a very satisfactory condition. The general state seems excellent, and the tumours have either receded or not increased. One of the patients had been operated on some years before for cancer of the stomach; the malady subsequently invaded the walls of the abdomen, creating a gastric fistula. Under the influence of the Doyen treatment, the fistula closed spontaneously.

The meeting was much impressed with the results of the anti-cancerous vaccination.

GERMANY.

Berlin, Dec. 16th, 1906.

AT the Medizinische Gesellschaft a discussion took place on Hr. Lewins', note on

ACOCANTHERA SCHIMPERI

reported in your issue of December 5th.

Dr. Stadelmann observed that at the suggestion of Hr. Lewin he had made some trials of the drug. First of all he used a decoction of the wood, 0.5 gm. to 150.0, but the dose was too small. Other modes of preparation, such as maceration, had proved useless. Going very cautiously by trials on himself and others he had arrived at a proper dose according to the following formula: Inf. acocanth. 1.0 to 160 grm.; Syr. Simp. 30.0; Aq. Menth. Pip. 10.0.

In this form it proved a slightly bitter medicine, but one taken readily and always well borne by the stomach.

Of the mixture he gave one tablespoonful every two hours and continued it for four to five bottles of it. If no effect was produced by this, none need be expected.

A total of 29 cases had been treated with it, amongst them the most varied forms of heart disease and nephritis.

Pulse and blood pressure were sometimes not affected at all, at other times very much, as happened also with digitalis.

The secretion of urine was sometimes increased, and the general condition frequently much improved.

Taken as a whole, acocanthera was an important substitute for digitalis and digitalin, to which it was sometimes not equal in activity, but which it sometimes exceeded very considerably. It had the advantage over digitalis that it did not lose its power by long keeping. Further investigation in the clinic should, however, be made with it, before it was introduced into general practice.

He had also given ouabain injections 0.004 to 10.0 grm. They caused no trouble and were given three or four times a day. The results appeared to be very fine, but the observations were not sufficiently numerous. If the efficacy was confirmed it would be a great gain, as the action was rapid, and digitalin injections had to be given up on account of their great painfulness.

Dr. Brieger had obtained from arrow poison a crystalline substance three times the strength of the poison itself. He doubted the chemical purity of Lewin's amorphous ouabain, and none but pure chemical substances should be introduced into medicine. It was a guarantee of purity when the substance was crystalline, and it must be our aim to procure such a substance There were several bodies with the name ouabain that were not identical, and there were also various species of acocanthera.

Hr. Franz Müller asked if investigation had been made as to whether, unlike strophanthine, it had but little influence on the walls of vessels, and if it was cumulative in action.

Hr. Lewin in reply maintained his original position.

Hr. P. Rosenstein reported the case of a young girl who had had

BOTH KIDNEYS OPERATED ON.

In a young girl whose right kidney had been extirpated for calculi he found stones also in the left. As she expressed a desire for operative relief, he decided to operate, but with reluctance. He opened out the left kidney and made an incision, the kidney having been first rendered bloodless, and removed 35 cystine calculi. It was remarkable that the kidney was scarcely enlarged; the parenchyma was very much thinned. He closed the kidney by suture, drained the pelvis, and closed the external opening with the exception of the part occupied by the drain. During the first two days not a drop of urine was passed, and the heart was very weak. Stimulants or excitants were freely given. The urinary secretion started on the third day. Recovery took place, and the patient might be looked upon as safe. Since the operation, three months ago, she had got quite well, and she had now a normal excretion of urine, both in quantity and quality.

Hr. H. Isaac showed a girl with a primary sore on the mamilla, and also one at the same time on the lower lip. The sores as shown by subsequent roseola were syphilitic. The speaker was of the opinion that extragenital syphilis had increased during recent years, and suggested an enquiry into the matter.

At the Gesellschaft fur Psychiatrie und Nerven Krankheiten

Hr. Plant, of Munich, spoke on

THE OCCURRENCE OF SYPHILITIC ANTIBODIES IN THE CEREBRO-SPINAL FLUID OF PARALYTICS.

His investigations had been carried out in association with Prof. Wassermann. It was ascertained that in the large majority of cases syphilitic antibodies were found in the cerebro-spinal fluid of paralytics, and in a smaller proportion in the serum also. In 38 out of 48 cases examined these antibodies were found. In six cases the investigation was negative, in four doubtful. In ten cases the serum could also be examined, and in all in which the antibodies were present in the cerebro-spinal fluid, they were found in the serum as well. Twenty-three non-paralytics had no antibodies. Among the cases in which the absence was not positive, the patient's history showed syphilis in some instances. There appears to be no binding connection beween the clinical facts and the biological condition. Old cases and recent cases behaved much in the same way It was a question whether the production of antibodies did not run in curves, so that at one time a positive condition was met with, and at another a negative. In 16 cases lymphocytes were looked for and found in all, but some of the cases did not show the antibodies. In four cases of cerebral syphilis the antibodies were not found with certainty. An old syphilitic without central symptoms gave a negative result. The result showed that the majority of paralytics were syphilitics, but nothing further could be said at present as to the connection between the two. In no case were there fewer antibodies in the cerebrospinal fluid than in the serum. If it could be determined that the antibodies had their origin in the central nervous system, then some syphilitic process must go on there.

Hr. Zieben spoke of the frequent remissions that took place in dementia paralytica as compared with brain syphilis, and suggested that comparative investigation should be made before and after the remissions. The negative result would show that only few antibodies were present, and that the alexin of the cerebrospinal fluid was completely withdrawn.

Hr. Plant, in reply to various speakers, said that mercurial treatment did no good, that Hr. Zieben's suggestion was a good one, and that it was yet too early to answer questions.

AUSTRIA.

Vienna, Dec. 16th, 1906.

OSTITIS DEFORMANS—PAGET'S.

KUTSCHA presented a patient to the Gesellschaft from Eiselsberg's clinic, with a form of osseous deformity recognised as Paget's. The subject was a female, æt. 56, who appears from the history to have been complaining for the last five years of pains of an indefinite character. A few months after the advent

of pain the bones of the legs began to swell, and still later the left arm. A few months after this she was attacked with severe lancinating pains in the back of the head and forehead, associated with vertigo and dulness of hearing, especially in the left ear. The head on measurement was greatly enlarged. During this time the ankles and bones of the legs were bending outwards and increasing in thickness, but the pain had ceased. On the other hand, the pain was intense in the upper arms and head, the latter often feeling as if it would split.

With the Röntgen rays cysts in the bony structure with a fine reticular web between were observed.

Fungus on Knee and Elbow Joints.

Salzer presented a girl, æt. 6, with a fungus on both elbows and knees, which he had treated with Spengler's tuberculin with good results. The child was greatly reduced, with right knee contracted at right angles, and much swollen. Both elbows were in a similar condition; from these three parts discharges of an offensive character exuded. The treatment has not long been commenced, yet the left leg is already in a state of extension. This limb was first bound with ointment till dry with the injections.

At first the dose was one-tenth of a milligram, and was very slowly increased, giving the minimum of reaction; only once was the temperature raised to 39° Centigrade. At present Salzer is injecting two milligrams, and has released the left elbow from its ankylosed condition; the right elbow has still a good deal of fungus about it, though far less than when the treatment was commenced, but the fistula still exists. The knee joint in extension is quite healed, and the swelling gone. Considering the severity of the case, he thought this was a wondrous improvement in so short a time. He anticipates a perfect recovery by a continuance of the treatment.

Röntgen Rays.

Benedikt showed a few Röntgen plates to prove that the rays were of more service to the clinician for diagnostic purposes than to distinguish bones, air passages, and soft swellings. Radiologists who could only do this were using defective apparatus, as exudations and blood effusions could easily be distinguished between the cranium and cerebral substance; even soft swellings can be easily recognised on the plates. He believed that with daily progress on the improvement of the instrument it would be easy to diagnose any trifling disturbance that was accessible by the rays.

Bilious Typhoid.

Kretz shewed a few blood preparations taken from a patient suffering from bilious typhoid in one of the Smyrna hospitals. On the sixth day of the disease a large number of recurrent spirochætæ were found, which proves that the classic bilious typhoid of Smyrna requires further bacteriological examination to determine whether the disease is connected with typhoid or identical with the icteric fever of the Orient, or should be isolated entirely from both as bilious typhoid.

Pathology of Atrophy.

Bum gave a report of his experiments with animals to determine the question whether disease and injury of a joint or the inactivity produced muscular atrophy. Paget attributed this to reflex tropho-neurosis, Salzer to inactivity. His experiments were overwhelmingly in favour of inactivity, although reflex influences played a part in the articular atrophy. It cannot be denied that neurotrophic changes in the skin, hair, nails, cellular tissue and bony structure are present.

Isenschitz said that Bum's results were not in accord with clinical experience. He related a case of fungus in the navicular bone where the muscular atrophy was entirely due to the morbid process, and not to inactivity.

We regret to learn that Mr. Walter John Sykes, M.D., of Westfields, East Grinstead, editor of *The Analyst*, and late medical officer and public analyst of Portsmouth, was found dead in bed on the 16th instant.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

PROPOSED COMPULSORY NOTIFICATION OF PHTHISIS IN EDINBURGH.

The Convener of the Public Health Committee makes the following statement in reference to the adoption of this measure:—Apart from notification to the local authority of every case in the district new powers are given to deal with the disease by the Infectious Diseases (Notification) Act. Every one competent to speak authoritatively recognises that compulsory notification is absolutely necessary to acquire complete information as to the extent of the evil. As to the procedure which will follow notification, the cases may, in general, be divided into two classes. First, when the doctor in attendance can guarantee that the patient can be properly looked after at home in the matter of disinfection of the premises, prevention of infection by the sputum, etc., nothing further will be done, except that the doctor will notify from time to time as to the progress of the case, and will instantly notify any removal, so that the house may be thoroughly disinfected before another tenant enters. Where the patient's circumstances are not such as to ensure that such measures will be effectively carried out, visits will be made by the inspector under the Medical Officer of Health. The house will be thoroughly disinfected, and the patient instructed as to what precautions he must take to prevent the spread of the disease. So long as the directions given are followed out the patient will be allowed to live in his own house. Compulsory notification will give information of every case in the city, and those which on account of their advanced stage are dangerous to the community will be removed to hospital.

A few more beds than the 50 set apart for phthisis will be required, but not more than 100 in all. The deaths from consumption in Edinburgh number about 400 annually. Taking the average duration of each case at three months, the 100 beds would provide accommodation for 400 cases in a year. It is impossible to state in advance accurately what the expense will be, but for the first year it is thought that two additional men in the Health department—an inspector and a disinfector—will be enough. This will absorb £120. With regard to notification fees there is a precedent from Sheffield. In 1904, when compulsory notification was adopted, there were 826 cases and 536 deaths; the following year the deaths numbered 490 and the cases 741. In Edinburgh the estimate is that the cases will not exceed 800, which with notification fees at 2s. 6d. and 1s., should not bring the total cost of the scheme to more than £300. There is no provision in the scheme for sanatorial care of early cases, for the cure of disease does not come into the general schemes of public health administration. The consumptive patient is not himself infectious; the danger resides in the sputum, and if that is looked after he is practically free from danger so far as the community is concerned.

On the motion of Councillor Macpherson it was agreed that the public health committee recommend the town council to obtain powers from the Local Government Board to place consumption under the infectious diseases notification act.

Administrative Control of Phthisis.—Some further explanation of the Local Government Board's circular have been furnished in a correspondence between the Secretary of the Board and a medical officer of health, which has been published in the *Scotsman*. In reply to a query by the latter as to the procedure to be adopted, and the advantages of compulsory notification, in the case of a local authority acting under the instruction of the Board, and treating phthisis as coming under the Public Health Act, Mr. Falconer Stewart writes: "I am to explain that phthisis as an infectious disease falls to be dealt with by the local

authority in the manner most appropriate to the character and the peculiar nature of its infectivity. It cannot be said that there is a method of procedure common to all infectious diseases. Each disease is dealt with in the manner considered best adapted to meet and combat that disease. The answer to the fourth question is that the extension of the infectious disease (Notification) Act to pulmonary phthisis does not confer greater powers on Local Authorities, but enables them to ascertain where cases of the disease exist.

Dundee and Treatment of Cancer.—It is announced that the Caird Cancer Hospital will be opened in a few weeks. Arrangements have been made for three wards being occupied, while a fourth is to be set apart for electrical treatment, the apparatus having been provided by Mr. J. K. Caird, the donor of the new hospital. It is hoped that soon a laboratory for the study of cancer will be started, and towards this end Mr. Caird has generously offered to guarantee £1,000 a year for five years.

Proposed New Dispensary in Anderston, Glasgow.—As was indicated a week or two ago, the proposal to open a new dispensary in Glasgow was opposed by the practitioners in the neighbourhood on the ground that it was not demanded by the requirements of the district. An independent inquiry into the conditions by the staff of the *Glasgow Herald* has led to a similar conclusion—that the creation of a new dispensary would lead to a vexatious and wasteful overlapping of philanthropic effort.

Notification of Births in Glasgow.—The corporation has elaborated a scheme for the compulsory notification of births within forty-eight hours. It was proposed to place the obligation to do so on the physician attending, but as no provision was made for the payment of a notification fee the scheme was opposed by the profession, and the clause has been dropped.

BELFAST

BELFAST DISTRICT ASYLUM: INSPECTOR'S REPORT.—This report, just published, contains several points of interest. One is the reference to the cause of death in the patients who died during the year. These numbered 99, and in 23 cases the cause of death was verified by *post-mortem* examination. In 17 cases, or almost 17 per cent. of the whole, death was due to general paralysis of the insane, while in only 9.9 per cent. was it due to tuberculosis. These figures are very different from those found in asylums in rural districts in Ireland. There are at present 11 men and 3 women under treatment for general paralysis in the asylum. Another point of interest is the description of the new villas at Purdysburn, now in full working order. In them 400 of the total of 1,114 patients on the books of the asylum are housed, and the results are most satisfactory. The villas are comfortable houses, and every appearance of restraint is avoided. Windows and doors are freely opened, and the patients help in the ordinary domestic work, under the direction of a nurse in each villa. The general surroundings are said to be homely, and the discipline and formality of public dining-halls is entirely absent. The results in Purdysburn are evident, the patients looking far brighter and happier than they usually do, and there is no doubt that the villa treatment will be extended to all suitable cases

LETTERS TO THE EDITOR.

TRYPSIN IN CANCER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Every medical man must deplore the frequent attempts which are made in the Lay Press to induce the public to believe that a cure for cancer has been discovered. Whenever an allegation of this kind is made it is doomed to excite false hopes in the minds of unfortunate sufferers, inasmuch as in the present state of our knowledge we are unable to promise any such consummation in the treatment of this disease.

My reason for availing myself of this opportunity of referring to the subject is based upon the facts that an article entitled "The Approaching Conquest of Cancer," purporting to deal with the treatment of the disease by trypsin, appeared in the *Pall Mall Gazette* last week, with the result that some publicity has been drawn to this question; and that last week, on December 12th, there appeared in the MEDICAL PRESS AND CIRCULAR a review of my small book on "The Nature and Treatment of Cancer" (*a*) in which you kindly say "my views on the treatment of cancer, and the work I have done on the subject, are so well known that there is no need to do more than mention that my little book has now reached a fourth edition."

What, however, is of more importance, and in contradistinction to the misleading notices in the *Pall Mall Gazette*, is your opinon that "the whole subject is still in a tentative condition, so that the wise course is still to suspend judgment; that my methods are being extensively tried (as you believe, and which I can affirm), and doubtless the experience of a few more years will decide how much of permanent value there is in them."

It seems a pity, as you, sir, have frequently pointed out, that the editors of lay newspapers and journals could not have attached to their staff a medical expert, to whom all matters of a professional nature sent to them by correspondents could be referred for instruction and guidance.

While my daily experience of the treatment of cancer by trypsin, alone or aided by other substances, continues to convince me of its efficacy in affording relief by causing an amelioration of the symptoms and in some cases actual arrest and diminution of the growth, I do not think I am justified in asserting that the treatment can be regarded as curative at the present time. It must take, and is bound to take a considerable time and many cases to arrive at any proper conclusion regarding the precise value of this treatment. Moreover, the trypsin treatment of cancer, as I have pointed out in my book, does not merely consist in the administration of trypsin or pancreatic extracts in one or other of its various preparations. I propose to publish shortly a further series of cases in which, so far, results have afforded room for the greatest encouragement.

If I presume to claim the right to speak on this subject, it is because that since the period I suggested this method of treatment I have been engaged in elaborating and placing it on a more satisfactory basis. In this connection I should like to recall to the notice of your readers the facts that I drew attention to the influence of the pancreas in cancer in the *Lancet* of January 14th, 1905; that previously to this my work was known to many and portrayed in my pamphlet, "Some Methods of Hypodermic Medication in the Treament of Inoperable Cancer" (October, 1904), also in the *British Medical Journal*, January 7th, 1905; that the treatment of cancer by hypodermic injections of trypsin and of pancreatic preparations was commenced by me on January 19, 1905, and these methods introduced to the notice of the profession in the *Lancet*, February 11th, 1905, and MEDICAL PRESS AND CIRCULAR, March 8th, 1905; that the suggestions which led me to this treatment were based on clinical and chemical considerations, and absolutely independently of any embryological work or theory.

I am, Dear Sir, yours faithfully,
J. A. SHAW-MACKENZIE, M.D. (Lond).

London, W., December 15th, 1906.

MEDICAL EVIDENCE IN THE LAW COURTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems to me probable that many who followed the evidence given in the Cardiff case by the medical witnesses have, like myself, felt some difficulty in understanding how it influenced the judge and jury in the verdict thus arrived at. The way in which Mr. Rufus Isaacs cross-examined Mr. Rose must have caused much amusement, or rather the way in which Mr. Rose gave replies to the questions that were put to

(*a*) "The Nature and Treatment of Cancer." By John A. Shaw-Mackenzie. M.D.Lond. Fourth Edition, revised. London: Bailliere, Tindall, and Cox. 1906.

him. In everyday conversation we experience the great difference there is between questions asked us by an ignorant and more or less prejudiced person, from those which the expert or the anxious inquirer may put to us. In matters medical every one almost has an opinion founded on some personal experience, or what has been learnt from others, and there is far less confidence placed on the advice and opinions of medical practitioners than upon those of the lawyers on matters of legal interest, though these very subjects are so much easier for ordinary persons to understand. We do not see lawyers put into the witness-box as doctors are, to give their views of the meaning and intentions of our laws, though we do see curious differences in the conclusions arrived at on the same case in different courts. It is probable that the old-fashioned course of "Lectures on Forensic Medicine," which was one that had to be signed up for in the late stage of hospital studies, was intended to prepare practitioners for the kind of evidence they might have to give in Law Courts, and the care they should observe in giving it. Now this kind of work is handed over to experts, and medical evidence of the ordinary practitioner is limited to the special details of the case in hand. It is usual, it may be noticed, in the cross-examination of the medical witness personally concerned, for questions to be chiefly asked, not on the actual facts stated in regard to the case itself, but upon the various theories or views held in the profession on the class to which the case belongs. And then, when experts are put into the box no questions are put upon the statement regarding the special case, for the simple reason that it has not been under their care; but the questions asked all bear on the views of this party or that in the profession, and the extent to which the injuries complained of may have arisen from ignorance or culpable neglect. In the Cardiff case some surprise must have been felt that such a strong array of expert evidence on the defendant's side should have apparently had but little influence on the jury, and the question arises whether it would not be far better to do away with expert evidence called by each side, and let one or more independent medical witnesses be appointed by the Court to give evidence, as is done in cases of lunacy when brought under the Lord Chancellor.

It is so natural that a hospital teacher should feel a personal interest in a plaintiff or defendant with whom he is more or less personally acquainted as an old pupil or friend, and consequently his evidence may not be altogether that of an unbiassed expert. In this age of reform let us hope that we shall see before long some improvement in the way in which medical evidence is conducted in our courts of law.

I am, Sir, yours truly,

A Former Lecturer on Forensic Medicine.

Pwllheli, North Wales.

THE GENERAL MEDICAL COUNCIL ELECTION

To the Editor of The Medical Press and Circular

Sir,—Will you permit me to express my gratitude to every one of the 1785, whether lady or gentleman, who has taken the trouble to vote for me, and to say that I do not regret having taken part in the fray; that many happy incidents have occurred, especially communications from old friends all over the country, and that the result will have no deterrent effect upon my efforts for the union and interests of the profession generally, and that I am glad to have had the opportunity of placing so prominently before the profession my views on essential matters in medical politics. It is just possible that organisation has carried the day rather than sound views without it. We in the north are perhaps too happy in our independence. Above all I must express my thanks to the medical press generally for the liberal grant of space, both for my friends and myself.—I am, sir, yours truly,

G. H. Broadbent.

Manchester, Dec. 12th, 1906.

To the Editor of The Medical Press and Circular.

Dear Sir,—I will thank you to permit me through your valuable columns to express my gratitude to the 3773 medical practitioners who during the election just concluded, recorded their votes in my favour. My thanks are specially due to those who have voluntarily worked for me for several weeks past in the hope to secure my re-election. I must confess to feeling disappointed at the result, as I had hoped that the recollection of past services—ten years as a medical councillor—would have had greater influence when voting papers were before the electors, but I am cheered by the reflection that more can be done for the profession and the public as a "free lance" than would be possible if wrapped in the constricting robes of a medical councillor. I have long felt that the battle of medical reform must be fought outside the Council Chamber. Again thanking you for your courteous indulgence,

I am, sir, yours truly,

George Brown.

Callington, Cornwall, Dec. 12th, 1906.

To the Editor of The Medical Press and Circular.

Sir,—Will you allow me, through your columns, to thank the profession in Scotland for the great honour it has done me in electing me as its Direct Representative on the General Medical Council. It shall be my earnest endeavour to warrant the confidence.

I am, Sir, yours truly,

Norman Walker.

Edinburgh, December 10th, 1906.

A NOTE ON THE ELECTION FIGURES.

Sir,—The number voting, whose votes were valid, is 10,249; and the highest number of votes given to any one is 4,861. That is, the successful candidates were elected by fewer than half of those voting. Under *Proportional Representation* one of the first three would have been elected and perhaps a second. For the second three the number of votes equals 10,247, so that one third of the voters would have elected one of the second three. I assume that the same voters voted for all the first three, and likewise for the second three. The votes given to the remaining four are thrown away. Their number is 5,741, or one-half nearly of all the voters. It would have been possible for one of them to be returned, instead of one of the first three, but perhaps unlikely. This is not by way of suggesting that the selected are not well worthy of our confidence. Not at all. But the figures invite consideration whether the election is as representative as it might be made.

I am, Sir, yours truly,

G. Crichton.

Lexham Gardens, Kensingtan, W.

Dec. 15th, 1906.

MEDICAL ASSISTANCE TO MIDWIVES.

To the Editor of The Medical Press and Circular

Sir,—I am directed by a Committee of the London and Counties Medical Protection Society, which is considering certain matters affecting the interests of medical practitioners, and arising out of the working of the Midwives Act, to invite members of the medical profession to assist by giving information individually on the following points:—

1. The number of instances, in a given time, in which each medical man has been summoned to the assistance of midwives, sending for him in pursuance of the rules of the Midwives Board.

2. What payment he received in each case, and from whom?

3. What was the nature of each case to which he was so summoned?

Will you kindly allow me to ask your readers to be good enough to send answers to the above questions, authenticated by the name and address of the sender, to me at the offices of the Society, 31, Craven Street, Strand, London, W.C.

I am, sir, yours truly,

Hugh Woods,

General Secretary.

THE MOUTH AS A FOCUS OF INFECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It seems a pity Dr. F. Norman did not point out in his excellent paper published this week that it is impossible to treat satisfactorily a mouth which is a focus of infection without the assistance of a dental surgeon. This remark applies especially to pyorrhœa alveolaris. The only effectual way to deal with the "pockets" around the teeth after removing the tartar, is to apply antiseptics direct to the parts. A patient cannot do this for himself, neither can it be done effectually by an unskilled operator. The *modus operandi* will be found described in dental text-books—very clearly in Sewill's manual. Perchloride of mercury and other powerful germicides may be thus used. Septic mouths among all classes of patients have increased in number with the growth of quack dentistry. The number of cases in which "bridge work" may be properly used is really very small. Artificial teeth fixed irremovably always cause extreme sepsis unless the remaining natural teeth and stumps be first brought into a perfectly healthy condition. The quack disregards this consideration, and often leaves roots, the causes and centres of suppuration, to lie hidden under the frames. Close examination of the mouths of many wealthy (often foolish) women, the victims of quackery, would often reveal to the medical attendant a state of things needing to be reckoned with both in diagnosis and treatment. Among the poorer classes it will frequently be found that a plate and clasps, composed partly or entirely of inferior metal, with still lower quality solder, is worn over fœtid stumps, and rarely removed for cleansing. The galvanic action of the metals aggravates the condition, and this is often bad enough to excite local disease, and to affect seriously the general health.

I am, sir, yours truly,

A HOSPITAL DENTIST.

London, W., Dec. 14th, 1906.

OBITUARY.

RICHARD SKINNER FOWLER, F.R.C.S.Edin., M.R.C.S.Lond., OF BATH.

One of the most popular medical practitioners of Bath died on the 9th instant. in the person of Mr. Richard Fowler, at the age of 76. In recognition of his services in the small-pox epidemic of 1858, the working men of Bath, to the number of 1,500, presented him with a testimonial and a purse of sovereigns. Mr. Fowler was born in Bath in 1830. Then, in January, 1855, he became house "apothecary" or house physician, at the Royal Bath United Hospital, and this office was his until March, 1859, the year after the small-pox epidemic just referred to, and in connection with which Mr. Fowler worked heroically in the special hospital. Then he sought private practice, and in 1867 was elected hon. surgeon. He resigned in December, 1890, and was then made hon. consulting surgeon, and in January, 1904, he was elected to fill the office of president. For 24 years Mr. Fowler was surgeon to the 1st V.B. Somerset L.I. Other positions which Mr. Fowler held included the vice-presidency of the Royal Medical College at Epsom; he was an honorary life governor of the Jews' Society; and a trustee of the Blue Coat School since 1894.

DAVID McKEOWN, M.D., R.U.I.

We regret to announce that Dr. McKeown, of Manchester, honorary medical officer of the Manchester Eye and Ear Hospital, died suddenly on Sunday week at Chinley, where he had been staying for the benefit of his health. He was 55 years of age. Deceased was a distinguished student of Belfast, and graduated M.D. Royal University of Ireland, with honours, in 1877.

JAMES PAUL RUDOLF LAMBERT, M.D.Edin.

We regret to record the tragic death of Dr. James Paul Rudolf Lambert. He was dragged under a railway carriage at South Kensington station and received such terrible injuries that he died an hour later at St. George's Hospital. By an irony of fate the station officials sent to his own house to summon him to attend the injured man. Deceased graduated M.D. of Edinburgh University in 1895, and M.B. in 1890.

ALEXANDER WAUGH, M.R.C.S.Eng., L.R.C.P.

We regret to record the death of Mr. Alexander Waugh, of Midsomer Norton, on December 9th. Dr. Waugh was born at Warminster on October 15th, 1840, and was, therefore, just over 66 years old when he died. His father, the Rev. James Hay Waugh, was rector of Corsley, Wiltshire. On leaving Radley College, he entered the Bristol Medical School, where he graduated from, and afterwards took his degrees at St. Bartholomew's Hospital. He lived in Midsomer Norton for 41 years, and was identified with every side of the life of the town. In 1880 he was elected president of the Bath and Bristol branch of the British Medical Association, being at that time the youngest man ever elected to that honour. He was for many years medical officer of health; and was conspicuously identified with the local improvements effected by the Local Board. Dr. Waugh was as popular in private life as in public. He was a keen sportsman, a fine shot, and an enthusiastic fisherman, and loved every form of manly recreation.

JAMES GRAY, M.A., M.D.Edin., F.R.C.S.Edin.

The death is announced of Dr. James Gray, one of Dundee's most promising surgeons, at the early age of 34. His end came suddenly, following upon blood-poisoning two years ago. Dr. Gray graduated M.A. at St. Andrews in 1892. The first two and a half years of his medical course were spent in Dundee. He obtained in 1895 the degrees of M.B. and C.M. at Edinburgh University with honours. Three years later Dr. Gray was elected a Fellow of the Royal College of Surgeons, Edinburgh. After graduation Dr. Gray was appointed junior demonstrator of surgery in Edinburgh University. When he returned to Dundee it was to take up the position of assistant to the Professor of Surgery in University College, and during the vacancy in the Professorship of Pathology in the College Dr. Gray acted as interim lecturer on practical pathology. In May, 1899, Dr. Gray entered into private practice, and until recently he was medical officer for the middle dispensary district in connection with Dundee Royal Infirmary, to which appointment he was elected in 1900. Five years ago he was appointed an assistant surgeon in Dundee Royal Infirmary.

GIUSEPPE LAPPONI.

On Friday, December 7th, at 6.20 a.m. died the Pope's body physician, Dr. Giuseppe Lapponi, who had acted in the same capacity to the Pontiff's immediate predecessor Leo XIII. Born at Tolentino in the Marches on April 16th, 1851, he was but 55 years old when he succumbed to an illness of some three years' standing—an illness obscure in its earlier stages, but latterly declaring itself as carcinomatous in character, affecting the liver and finally the spleen. With the energy and devotion to duty which belonged to him he remained at his post long after it was wise or prudent in him to do so—till, in fact, his distinguished patient had plainly to tell him that, of the two, the doctor was most in need of medical aid. He continued, however, his periodical visits within a few days of each other at the Vatican, so far yielding to the Pope's kindly insistence as to take to bed immediately afterwards. But the end was not distant, and on the morning of December 3rd, on returning from a short drive, he was seized with acute rigors, coincident with a raised temperature. Dr. Marchiafava and Dr. Gallenga, who attended him, found him in the initial stage of bilateral pleuro-pneumonia, and from the first, though unremitting in their care, took the most desponding view of his case. An apparent rally on the Thursday (the 6th. was not maintained, and he sank rapidly, while pre-

serving the clearness of his faculties, till, as stated, he passed away in the early morning of the 7th, his wife, his son, his daughter, and Dr. Gallenga being at his bedside.

RICHARD WILLIS, M.R.C.S.Eng., L.S.A.

We regret to announce the death of Mr. Richard Willis, at his residence Horrabridge, Devonshire, on December 4th, from pneumonia, following influenza. Deceased, who was the son of the late Mr. John Willis, of Plymouth, received his medical education at Guy's, and qualified M.R.C.S.Eng. in 1842. Mr. Willis shortly afterwards settled at Tavistock, and had the largest practice in the district. He was for many years a member of the Tavistock Board of Guardians and other local bodies. He retired from active practice some years ago, and took up his residence at Horrabridge, where he died in his 87th year.

REVIEWS OF BOOKS.

SAVILL ON NEURASTHENIA. (a)

ONE takes up a work on neurasthenia with a certain misgiving. The subject has been so mauled by irresponsible writers who contributed nothing original to our knowledge of this protean malady that one despaired of further light being thrown on its etiology—and it is the etiology that matters, because there can be no sound treatment until this problem has been unravelled.

Now the author really does attempt something in this direction, and his arguments are not merely "views," since they are based on an imposing number and variety of personal observations. To him, we believe, belongs the credit of pointing out the connection between the condition known as neurasthenia and certain toxic states of the blood, though this was for a long time hotly contested by admitted authorities. Now a fertile source of "toxic blood states" is to be found in the gastro-intestinal tract, and disturbances of function in this area were forthwith incriminated by the author as the original source of the depressing toxins. In the present edition he goes even further, and, by very painstaking investigation of a series of private cases, has analysed the relative frequency of various toxic conditions in the production of neurasthenia.

The importance of this departure will be recognised if we bear in mind that, hitherto, physicians have for the most part been content to treat the functional derangement of the nervous system—neurasthenia—by rest, psycho-therapy and other measures empirically directed to the improvement of the nervous symptoms—in short, by symptomatic treatment. Dr. Savill, on the contrary, aims at the identification of the cause, with a view to its preventive and curative treatment. This gives his work the stamp of originality, and will secure for him a sympathetic reception from practitioners. The scope of treatment is thus considerably enlarged and its chances of success correspondingly increased. The author provides us with well-thought-out schemes of treatment, each adapted to the particular etiological variety, and for that we cannot but be grateful. It is emphatically a practical guide to the treatment of neurasthenia, based on a solid foundation of direct observation.

New System of Hospital Accounts.

A CIRCULAR of much importance to medical charities employing what is known as the uniform system of hospital accounts has been recently issued jointly by King Edward's Hospital Fund, the Hospital Sunday Fund, and the Hospital Saturday Fund. The statistics now required from hospitals applying for grants has brought to light various defects, and the whole subject of hospital accounts was reported on at the Prince of Wales's request by Mr. J. G. Griffiths, F.C.A., last year. This report was subsequently referred to a committee of hospital secretaries, presided over by Mr. Ryan, of St. Mary's Hospital. The three Funds have now issued an official statement containing particulars of the revised system, which will come into force on January 1st next, and which all institutions applying for grants from these Funds will be required to adopt. The circular contains, in addition to the form of income and expenditure account, a model balance-sheet and statistical tables, with a full index of classification, giving the headings under which the various items of expenditure are to appear. Full explanations of the changes in the old system are supplied. Copies may be obtained from the publisher, Mr. G. Barber, 23, Furnival Street, E.C., price 1s. post free.

(a) "Clinical Lectures on Neurasthenia." By Thomas D. Savill, M.D.Lond., Physician to the West End Hospital for Diseases of the Nervous System, Assistant Physician to the West London Hospital. Third Edition. London: H. J. Glaisher. 1906.

MEDICAL NEWS IN BRIEF.

Royal College of Surgeons of England.

AT an ordinary meeting of the Council of the College held on Thursday last, Mr. Henry Morris, President, in the chair, the congratulations of the Council were given to Sir John Tweedy, the late President, upon receiving from his Majesty the honour of Knighthood. A vote of thanks was passed to Mr. and Mrs. Bischoffsheim for their munificent gift of £40,000 to the Imperial Cancer Research Fund.

The Standard of Preliminary Education.—The resolutions passed at the recent meeting of Fellows and Members relating to the questions of admitting members to direct representation on the Council and admitting women to the College examinations were considered and are still under consideration of the Council. With regard to the third resolution passed at the same meeting relating to the raising of the standard of the Preliminary Examination in General Education and in Science, and the treating of chemistry, physics, and biology as matters of preliminary education, the Council decided to submit the following observations for the information of the Fellows and Members:—

The Standard of General Education.—With regard to the suggestion that the standard of the examination in general education be raised, the Council would remind the Fellows and Members that, so recently as 1900, steps were taken with this object. From the beginning of that year the General Medical Council ceased to recognise, for the purpose of registration, the first division Second Class Certificate of the College of Preceptors. As pointed out by the Council in their report to the Fellows and Members in 1901, a decrease of 305 in the number of students registered during the year after passing the examinations of the College of Preceptors immediately ensued upon this alteration, while an increase of 40 in the number of students registered after passing the Preliminary Examination of the Educational Institute of Scotland was noted; In view of these facts the Council think that, so far as this division of the United Kingdom is concerned, it would be inexpedient at the present time to still further increase the difficulty of the examination in general education.

Again, as regards the suggestion that the standard of the Preliminary Examination in Science should be raised, the Council would remind the Fellows and Members that in this matter steps have been taken even more recently. During the years 1903 and 1904 the Council, in association with the Royal College of Physicians, devoted much time and attention to the regulations relating to the first year of the medical curriculum and the examination in the subjects of Chemistry, Physics and Biology studied during that period. After consultation with the teachers in those subjects at the several medical schools in England, and the past and present examiners, revised regulations, effecting a complete re-arrangement of the examination, and materially raising its standard, were adopted. These regulations came into force in March, 1905.

With reference to the opinion that Chemistry, Physics and Biology should be treated as subjects of preliminary education and an examination be passed in them before the commencement of medical studies, the views of the Council upon this question, and their reasons for forming them, are fully set forth in the last annual report of the Council.

The thanks of the Council were given to Sir Victor Horsley, F.R.S., for his very interesting and valuable report upon the brain of Professor Babbage, a specimen in the museum of the college.

The Museum Committee reported that Vol. III. of the revised edition of the Physiological Catalogue was now ready for press, and it was decided to publish it with illustrations. The Committee was also authorised to consider and report as to what steps it is desirable to take with a view to preparing a new edition of the Pathological Catalogue.

A report was received from the Committee of Management submitting recommendations in regard to the examinations of the London School of Tropical Medicine.

"Peculiar People" and their Child:

AT Grays Police Court on December 7th, William Thomas Clark and Jane Clark, members of the "Peculiar" People, Grays, were charged with the manslaughter of their daughter Emily, aged seven. Herbert Henry Carter, an elder of the "Peculiar People," was charged with aiding and abetting.—Mr. Donald Maclean, M.P., who prosecuted on behalf of the National Society for the Prevention of Cruelty to Children, stated that Clark saw Dr. Ward and asked him to examine the throat of the child, who was found to be suffering from diphtheria. Clark said he did not want the child medically treated. The doctor advised medical treatment, and that the child be sent to hospital. Clark hesitated, and said he would let him know in two hours. Subsequently he went to the doctor's surgery with Carter. The doctor was informed that it had been decided not to send the child to hospital, and an antiseptic for the throat was also refused. The child died from heart failure produced by diphtheria. If properly treated, said counsel, the child's life would probably have been saved, as the case was of ordinary severity. Whilst the child was ill Carter anointed her and prayed over her, and it was submitted that Carter, by his position, influenced the two other defendants with regard to medical aid. After a lengthy hearing the defendants were committed for trial at the next assizes. Carter stated that he had helped the parents out of sympathy, and had not influenced them in any way.

Employment and Disease.—The Insurance of the Worker.

BEFORE the Insurance Society of Manchester last week. Dr. Dearden read a paper on "Diseases of Occupation from an Insurance Standpoint." Dr. Dearden recognised that, broadly speaking, industrial disease should cover any illness in the causation of which the trade of the patient was a factor, but to include all cases which came within this definition as qualified for compensation would, he thought, lead to injustice in some cases, imposition in others, and the expenses of litigation in most. It would be better to go in wholly for the German system than to attempt such a course. The difficulties of deciding such cases as whether a man contracted bronchitis or consumption in the exercise of his work or otherwise would be insurmountable. There were, however, certain definite dangerous trade processes with respect to which the risk of illness was very well understood, and concerning which the symptoms attributable to the particular noxious elements were well defined. The people engaged at these processes were just as much entitled to compensation when made ill through working at them as if they were the victims of accident. Why should these people be deprived of that to which they were entitled because of the difficulty of assessing the extent of responsibility of employer and employed in cases concerning which our knowledge was not so exact? It was quite possible, he thought, to avoid a definition of insurable industrial disease altogether, and simply schedule a list of diseases arising out of well-understood trade processes. He pointed out that the present Government had included in the Workmen's Compensation Bill provision for compensation on the occurrence of disease caused by certain sche-

duled processes, and he thought a great deal of good would accrue from the Bill if it passed into law. The Factory Acts had to be built up gradually to their present pitch, and so would these dangerous trades regulations. That the Government intended to do all it was possible to do to place other industries on the schedule was evidenced by the appointment of a departmental Committee to report on the matter.

Polyclinic Dinner.

The eighth annual dinner of the Polyclinic took place at the Trocadero last Wednesday, and in the number of diners, the distinction of the guests, and the vivacity of the proceedings, it was well up to the level of former years. The dinner committee were fortunate in obtaining Professor Clifford Allbutt for the chairman, for his name is sufficient in itself to attract all those who have the interests of medical education at heart. Mr. Henry Morris, as President of the College of Surgeons, was on the chairman's right, and Sir Alfred Keogh, K.C.B., on his left. Other well-known members and guests present were Sir Felix Lemon, Dr. Theodore Williams, Surgeon-General Branfoot, Dr. Dundas Grant, Mr. Malcolm Morris, Mr. Bidwell, Mr. Mayo Collier, Dr. Fletcher Little, Mr. James Cantlie, Dr. James Taylor, Mr. Keetley, Mr. Marcus Gunn, Mr. MacLeod Yearsley, and Captain Hayward Pinch, the Secretary. A number of ladies were present, some of them members of the Polyclinic, and some guests. After a particularly well-chosen and well-served dinner, the chairman gave the usual loyal toasts, and proceeded to propose the success of the institution in support of which the evening had been organised. Professor Allbutt dwelt chiefly on the advantages of post-graduate teaching, especially when divorced from elementary teaching. He praised the old method of instruction by disputation, and hoped that as far as convenient it would form the model on which the post-graduate classes were conducted. As head of a medical school almost purely scientific in its curriculum, he felt more and more the value of well-founded empiricism, and he urged all students of the Polyclinic to force to the front the facts and deductions they had gathered at the actual bedside of patients. The pathologist, he concluded, dealt with organs and tissues irreparably damaged; the finest practitioner was he who recognised disease in its early manifestations, and nipped them in the bud. Captain Pinch, in replying, pointed out that it cost a man two-thirds of a penny a day, or fourpence a week, to belong to the Polyclinic. There was no better investment in the profession. Mr. Cantlie, in a breezy speech, proposed the guests, for whom Mr. Morris and Sir Alfred Keogh replied. The final toast was that of "The Chairman," given by Dr. Theodore Williams. Vocal music was emitted at intervals during the evening.

An Action Settled.—Lady and Hydropathic Establishment.

In the King's Bench Division, last week, Mr. Justice Grantham had before him an action brought by Mrs. Merton, of Hans Crescent, South Kensington, against Dr. Ferguson, of a hydropathic establishment at Great Malvern, to recover damages. Mr. Montague Lush, K.C., for plaintiff, after a lengthy consultation between the judge, counsel, and the parties, said he was glad the parties had been able to come to a settlement. The action was for damages for a very heavy loss sustained by plaintiff. Mrs. Merton and her two sons, who were attending Eton, went to the hydropathic establishment of Dr. Ferguson, at Great Malvern, and while there contracted typhoid fever. One of her sons died as a result. The amount of plaintiff's out-of-pocket expenses was £1,250, and that amount had been paid by defendant into court, and he had also agreed to pay taxed costs. Mrs. Merton was now willing that the case should terminate, her desire to call public attention to the dangers run by the public having been effected. Mr. M'Call, K.C., for defendant, said he also was glad they had been able to avoid such an inquiry, which must of necessity be of a painful and profitless character; but he must say that his client was not directly responsible in this matter. What happened was due to the negligence of others, and that would be a question to be tried hereafter. His Lordship entered judgment for plaintiff with costs.

Cancer Research in Dundee.

Through the gift of a new building primarily intended for the purposes of a cancer hospital the accommodation in Dundee Royal Infirmary will be increased 50 per cent. The donor is Mr. J. K. Caird, LL.D., jute manufacturer, and the intention is that three of the wards should be occupied by patients, while in the fourth apparatus, also provided by Mr. Caird, will be fitted for the electrical treatment of patients. The directors have also a project in hand for cancer research, and towards this scheme Mr. Caird has guaranteed £1,000 a year for five years.

Anthrax in Liverpool.

A second death from anthrax, occurring within a week, was recently investigated by the Liverpool coroner. Joseph Henry Tomlinson, a dock labourer, æt. 28, had been working in the hold of an American liner, assisting in the storage of bales of dry hides en route from Rangoon to New York. On Thursday he received a scratch on the shoulder, caused by a nail, and next day, after working among the hides, he complained of pain. His wife applied a poultice to the scratch, which had become inflamed, and a doctor was summoned, who pronounced the man to be suffering from anthrax. An operation was performed in hospital, but the man died next day. A question being raised as to the use of gloves for handling hides, it appeared that regulations as to anthrax were posted up at the dock, and the steamship company had formerly distributed gloves among the men, but these were gradually discarded, and now it was left to the men to ask for them if they preferred to use them. In future the men would be required to use gloves when handling hides and skins. A verdict of "Death from anthrax" was returned.

A Medical Man sent to Penal Servitude.

Arthur Raynor, 57, physician, indicted at the Central Criminal Court on December 12th, for using an instrument, or certain means unknown, with intent to procure the miscarriage of Anne Lilian Martin, was sentenced to three years penal servitude by Mr. Justice Lawrance.

Royal College of Surgeons of England.

The following members of the college, having passed the required examinations and conformed to the bye-laws were admitted Fellows of the college:—Edward H. Douty, M.R.C.P., Lond., William J. Richards, L.R.C.P., Lond., Hugh M. Davies, L.R.C.P., Lond., Arthur de Silva, L.R.C.P., Lond., Alfred Ed. Johnson, M.B., Vict., Gwynne E. O. Williams, M.B., Lond., William Taylor, M.B., Lond., Bernard B. Riviere, L.R.C.P., Lond., Henry Gilbert, M.B., Melb., Harold P. Gibb, L.R.C.P., Lond., Robert F. Moore, L.R.C.P., Lond., Ernest C. Hughes, L.R.C.P., Lond., Harold T. Mant, M.B., Lond., Robert Milne, M.B., Lond., Walter W. Moore, M.B., New Zealand Univ., Reginald A. Greeves, M.B., Lond., Percy K. Steele, M.B., Vict.

Diplomas in Dental Surgery were granted to the following candidates:—Matthew Alexander, Arthur R. B. Allen, Albert E. S. Austin, Francis W. Bartle, Russell Beadnell-Gill, Frederick A. Beckley., Howard D. Clapham, Samuel S. Cooper, Edward L. Councell, Gwilym L. Davies, John R. D. Ditch, John H. R. Edward, Gordon Fryer, George B. Geake, Frank Giles, John P. Glassington, Trevor Griffiths, John E. Hanna, Edgar E. Houghton, Percy Howard, Arthur E. Ironside, Herbert E. Jackson, Charles E. Lloyd, Maurice J. Maguire, Ivor Margolies, Herbert R. Mays, Claude Miller, Frederick C. Nichols, Reginald J. Oliver, George Packham, Arthur H. Pickett, Ronald R. B. Ponder, Edmond L. Renton, Norman V. H. Riches, Oscar J. Roots, Walter D. Southern, Norman Y. Tessier, James G. Townsend, Gladstone Warren, Bargrave Weaver, Stephen J. Wright.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT GYNÆCOLOGICAL AND OBSTETRICAL LITERATURE

The Prophylaxis of Puerperal Eclampsia.—Hardie (*Jour. Obst. and Gyn.*, November, 1906).—The writer first mentions the familiar premonitory symptoms and signs—headache, vomiting, giddiness, and œdema of the ankles, while, if convulsions are impending, there are more pronounced cerebral symptoms, œdema of the face, and severe epigastric pain. We inquire about the urine, and find that it has been scanty, that it has a variable specific gravity, and that albumen is present. True, albuminuria is said to be sometimes absent, though personally I have never failed to find it, and this corresponds with the experience of Jardine. On the other hand, it does not follow that albuminuria necessarily leads to eclampsia, or that the actual amount present is of much prognostic significance, as the albuminuria and severity of the eclampsia are not co-related in any constant manner. It is specially needful when albuminuria is present to ascertain the quantity of urine passed in 24 hours. This is valuable in its relation to the specific gravity and amount of urea and urates excreted, for while the specific gravity may be apparently high enough, it is really low for a concentrated urine. The higher it is the more hopeful the outlook, as it indicates a larger excretion of urinary salts. The presence of blood and granular casts is, of course, of great importance. As preventative measures, much may be done during the early months of pregnancy by taking outdoor exercise, a glass of cold water night and morning in addition to ordinary fluids of the day. Cold bathing every morning during the summer months, at least; but towards the end of pregnancy warm baths are to be preferred. The bowels should be moved daily, and in the last two months of pregnancy only one nitrogenous meal should be allowed in the day. Should there be any indication of renal insufficiency or other premonitory symptoms —(a) In an early stage (subacute toxæmia), reduce the intake of nitrogenous foods and substitute fish and fowl for butcher's meat and eggs, reducing at the same time the amount of farinaceous foods. A glass of water is given four times daily between meals. Should the albumen increase under this diet, the patient is kept on skimmed milk and farinaceous foods alone, together with fresh fruit and vegetables, and rarely in obstinate cases the farinaceous foods are omitted. Drugs play but a very secondary part. The necessity for diuretics depends on the amount of urine passed, the citrate and acetate of potash being the best. To aid the metabolism of nitrogenous substances by thyroidin administration sometimes gives brilliant results and sometimes negative; the daily evacuation of the bowels should be regulated by aperients. (b) In the late stage (acute toxæmia). First in importance comes the withdrawal of food altogether, including milk, for from 24 to 48 hours, water alone being given, and where there is not much œdema, in large quantities, saline injections into the rectum are also given; unless the œdema is marked, Epsom salts are given in drachm doses every hour until a free evacuation occurs, and the acetate and citrate of potash as diuretics. The question next arises, should labour be induced? It is certainly better not to induce it for at least 36 hours, because the uterine contractions of labour might precipitate the convulsions.

F.

Early Tubal Gestation.—R. Hamilton Bell (*Jour. Obst. and Gyn.*, December, 1906).—This paper is based on the writer's experience of tubal gestation obtained from a record of 88 cases. An abstract of each case is given, and the following conclusions as to diagnosis and treatment are drawn. The diagnosis of tubal gestation, followed by tubal rupture or tubal abortion, is by no means rosy, and a number are regarded as cases of peritonitis or inflammation and abortion. In a woman between 20 and 40, after missing one or two menstrual periods, a very important symptom is abdominal pain, situated in one of the lower quadrants of the abdomen, sudden in onset, and severe in type—so severe, indeed, as to be commonly associated with faintness, or vomiting, or both. Concurrently with the pain, or shortly before, or shortly after, vaginal hæmorrhage begins, and continues irregularly day by day. The amount is small, the colour is dark, and is so characteristic as to be almost pathognomonic. Sometimes a definite cast of the uterus is passed, and in many cases there is later a slight pyrexia, and there may be difficulty with micturition. If rupture of the tube has occurred, with great internal hæmorrhage, there will soon be signs of excessive bleeding; but in the great majority of cases, whether of rupture or of abortion, the hæmorrhage is only sufficient to produce a pelvic hæmatocele. The characteristic physical signs of this condition are that the uterus is pushed forwards, and perhaps a little to one side, cervix softened, and body of uterus slightly enlarged, and that behind it, and probably more to one side than the other, is an elastic swelling depressing Douglas's pouch and the vaginal roof, and varying in consistence and tenderness. The table shows that no reliance can be placed on a history of sterility. Passing to treatment, the table shows that the surgical and not the expectant treatment has been adopted almost exclusively when the diagnosis was certain, or nearly certain. Contrasting the results obtained with those of a neighbouring observer who adopted the expectant treatment as far as possible, 83 per cent of abdominal sections gave a total mortality of 3.4 per cent., as against 9.3 per cent. in the latter series, where the percentage of abdominal sections was only 34.7.

F.

The Treatment of Inflammatory Tumours of the Adnexæ is considered by Steffock (*Münchener Med. Woch.*, 1905, No. 50). He deals first with the conservative treatment, and then with the operative. For the latter he recommends the vaginal route, by which (a) incision (b) extirpation of the adnexæ alone, or (c) extirpation of the uterus and adnexæ, or of the uterus alone may be performed. The first procedure is indicated by tumours of the tubes only in young women. The second, when old chronic tubo-ovarian tumours are present, and the technique is as follows: Anterior colpotomy through which the uterus is drawn forwards. Separation of the tumours from the adhesions, removal of the tumours, which may be opened if necessary. In this way one does not operate in the dark. After 80 such operations, the author had only one death, and this was not due to the operation. The removal of the uterus must be reserved for those cases in which both the uterus and adnexæ are diseased; but whenever it is possible it is better to take away the uterus in addition to the adnexæ when the latter must be removed.

G.

Prognosis After Operation for Carcinoma of the Vulva.—Grünbaum (*Deutsche Med. Woch.*, 1906, No. 7) reports on the various operations performed during the last eight years, for this disease in Landau's Klinik, Berlin, and comes to the following conclusions:—A lasting freedom from recurrence is to be expected in several cases after radical operation, even though metastases have already appeared in the inguinal glands. In order to obtain the best possible results the incision in every case must be made well outside the disease, and the inguinal glands, together with the fatty tissue surrounding them, must be removed from

both sides, whether any alteration is to be felt in them through palpation or not. G.

The Tarnier Maternity Hospital.—The statistics of this hospital for the year 1905 are recorded by Perret (*L'Obstetrique*, 1906, No. 2-4). There were 1,679 patients treated; 26 of these gave birth to twins, and 86 were treated for abortion. The presentation was vertex 1,540 times, face 5 times, pelvic 59 times, and transverse 15 times. In 85 cases there was narrowing of the pelvis, 54 times the conjugata vera being 10.5 cm., 15 times from 10.5 to 9 cm., 16 times 9 cm., or less. Hæmorrhages during pregnancy or parturition occurred in 10 cases. There were 5 cases of placenta prævia, and one of eclampsia. The placenta had to be removed manually 35 times. There were 77 cases of atonic postpartum hæmorrhage. Prolapse of the cord occurred 16 times, and prolapse of the arm twice. The forceps were employed 77 times, version 33 times, curettage 70 times, accouchement forcé 3 times, perforation 3 times, Cæsarian section 4 times, suturing of the perinæum 28 times. The complete morbidity was 16.2 per cent., when due to uterine infection 3.8 per cent. The complete mortality was 0.6 per cent., that due to uterine infection being 0.23 per cent. Five women died from septicæmia, one each from peritonitis, double-sided pyelo-nephritis, uterine rupture and tuberculosis, 2 from hæmorrhage. As regards the children, 31 died during labour, 30 during the first 24 hours, and 5 in the following 24 hours. Five were mascerated when born. Of those which remained alive 150 were very weakly. The infantile mortality was 3.3 per cent.; 22 died from bronchopneumonia, 7 from septicæmia, 5 from erysipelas, 4 from asphyxia, 3 from congenital debility, 2 from malformation, and one each from syphilis and convulsions. The infantile morbidity was 16.8 per cent. Seven infants weighed less than 1,500g., 5 of these died; 32 weighed 1,500-2,000g., 8 of these died; 111 weighed 2,000-2,500g., 11 of these died. The mortality among these weakly infants was 16 per cent., the causes of death being congenital debility 11 times, syphilis 3 times, bronchopneumonia 8 times, and one each septicæmia and erysipelas. G.

Internal Podalic Version for Shoulder Presentation.—Concerning this question, Demelin *L'Obstetrique*, 1906, No. 2-4) writes that when the shoulder presentation is diagnosed during parturition, while the membranes are still intact, every precaution must be taken to prevent rupture of the membranes. One may try external version very carefully, but vaginal examination and any method of artificially dilating the cervix must be avoided as much as possible. In no case is Braxton Hicks' version to be performed. The woman is to be put to bed, and the more or less complete dilatation of the cervix is to be waited for, in order that internal podalic version may be chosen. When the membranes are ruptured, and there is no contra-indication to version, it is to be performed when the cervix is fully dilated, or at least sufficiently dilatable. If, on the other hand, the cervix is not yet sufficiently dilated, it must be dilated gradually with the hand till the latter slips gently into the uterus and the version can be performed. In such a case immediate extraction of the child is never to be adopted. The full dilatation of the cervix is to be waited for, and the expulsion of the child left to nature. When one is careful not to pull on the child too soon, there will be no danger that the cervix, no yet fully dilated, will surround the neck of the child and keep the head from being born. G.

Veronal in the Vomiting of Pregnancy.—Rowlands (Lichfield) (*Brit. Med. Journal*, November 24th, 1906). A healthy primipara, æt. 29, pregnant two months, developed serious vomiting; nothing was retained by the stomach, and sleep was rendered almost impossible by the retching. All food was stopped by the mouth on finding that iced champagne, effervescing saline mixtures and other remedies proved useless, and rectal feeding adopted. As the pulse became rapid and weak strychnine was given hypodermically. Pot. brom., xxx grs., was given in one of the nutrient injections, and repeated in two hours, but without any effect, and morphia, ¼ gr., also failed to produce a change. At the end of three days veronal, xxxii gr., in powder, was administered in a nutrient enema. The patient fell asleep within half an hour, and continued to sleep for eleven and a half hours, and at intervals for the next six, rousing up during the administration of nutrient enemata. There was no return of the vomiting for twenty-five hours, and when it recurred it was markedly diminished in severity. During the following ten days Brand's essence, kreochyle lime water, and barley water in small quantities were given, and retained occasionally for a few hours. At the end of that time sleep was only obtained in snatches of from one to one and a half hours, and as the patient was not getting on, another dose of veronal in the same quantity was given by the rectum, which induced sleep for ten and a half hours. A purpuric rash was noticed on the arms, which, however, passed off in twenty-four hours. The vomiting recurred at intervals, but gradually the patient was able to take more varied nourishment by the mouth, in addition to the nutrient injections, which were continued for some time. Sleep was obtained naturally in gradually increasing periods daily, and in one month from the commencement of the illness the patient was convalescent. Quickening took place normally, the patient remaining well. It is pointed out that the case is of interest both from the gravity it assumed and the beneficial results obtained from large doses of veronal per rectum at a time when induction of abortion was seriously under consideration. H.

Painless Labour.—Scott-Dickson (Dundee) (*Brit. Med. Journal*, December 1st, 1906) describes a case of this nature. The patient, a five-para, æt. 38, none of whose previous pregnancies had reached full term, ranging from the fourth to the eighth month, stated that the membranes had ruptured, and she therefore concluded that labour had commenced. A vaginal examination revealed the fact that the os was about the size of a five shilling piece, and that the head was fixed. The patient walked quietly about the room for about an hour and a half, but stated that at intervals of about fifteen minutes she had a desire to defœcate. During one of these periods a hand on the abdomen showed the uterus to be contracting. Another vaginal examination proved the os to be fully dilated, and the head descending. The patient was then kept in bed, and an hour later the child, a full-term average-sized female, was born alive. Just as the head passed through the vulva a slight pain of a "cutting" character was noticed. Quarter of an hour later the placenta was expelled painlessly, followed by a large gush of blood, but the uterus contracted well. H.

Epithelioma of the Clitoris.—Leigh Day (Colchester) (*Brit. Med. Journal*, December 8th, 1906) records a case of the above. The patient complained of irritation of the vulva, and scalding after micturition, with pain in the genitals. She further stated that there was a lump present. There was no hæmorrhage nor discharge. Upon making an examination a scarlet mass was discovered springing from the prepuce of the clitoris, and very tender to the touch. An operation for its removal was performed, and the mass proved to be a squamous-celled epithelioma of the clitoris. Until four months previous to the patient's seeking advice, nothing had been noticed. She was then troubled with pruritus. The mass was not noticed until two months before operation, which pointed to rapid growth. The patient's age was 60; she had borne eleven children, and the menopause occurred at 41. H.

It is reported that a London medical man, Dr. Albert Shaefer, is lying in a Paris hospital as the result of a murderous assault in the streets, apparently from motives of robbery.

NOTICES TO CORRESPONDENTS, &c.

☛ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

CANADIAN.—Alas! there is no sort of way of getting at the person named. There is no specific designation in the title "Nurse," which is open freely to everyone who likes to assume it. It carries no guarantee of any kind, and is purely complimentary. If the woman named pretended to have a proper hospital certificate of three years training, and was engaged on that understanding, it might be possible to prosecute her for obtaining money under false pretences. A solicitor would advise you as to this, but we should not be very sanguine as to the result. When you have had a little experience of the British law you will find it is very lenient to a certain class of offenders.

M.R.C.P. (Brighton).—The advice of the medical man in attendance is likely to be sound as regards the question of operation. In any event, laparotomy is likely to be attended with no untoward results. It is hardly needful to add that any opinion as to the merits of the individual case, without a personal examination of the patient, must be extremely tentative and guarded.

SUCH IS FAME!

A CORRESPONDENT sends us the following account of an incident which happened to himself. Lecturing to a London County Council First Aid Class of shop assistants and servants recently, he came to deal in due course with the treatment of wounds and the use of antiseptics. Wondering how far the fame of Lister had filtered through to the lower middle classes, he inquired who it was who first discovered the value of antiseptics. There was a general puckering of brows for a few moments, then one better informed than the rest smilingly asked permission to speak. "Yes," said the lecturer, "who was it?" "Sanitas," replied the maiden.

SACCHARINE.—You will find a good deal of information on the subject of diabetes following fracture of the skull in a paper in Vol. LVII. of Guy's Hospital Reports.

Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 19th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. J. Cantlie: Clinique (Surgical).

THURSDAY, DECEMBER 20th.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Hutchinson: Clinique (Surgical).

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester Square, W.C.).—6 p.m.: Chesterfield Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions; I., Urticaria; II., Pemphigus; III., Pompholyx; IV., Varicella.

FRIDAY, DECEMBER 21st.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 p.m.: Operations. 2.30 p.m.: Dr. R. Bradford: Medicine. 3.15 p.m.: Mr. McGavin: Surgery. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 12 noon: Skin.

SATURDAY, DECEMBER 22nd.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnough Hospital, Greenwich).—2.30 p.m.: Operations. Out-patient Demonstrations:—10 a.m.: Surgical and Medical. 11 a.m.: Eye.

Vacancies.

County of London.—Horton Asylum, Epsom, Surrey.—Epileptic Colony, Ewell, Surrey.—Medical Superintendent of Horton Asylum, Epsom, Surrey. Salary £1,000 a year, with an unfurnished house. Applications to H. F. Keene, Clerk of the Asylums' Committee, London Asylums' Committee Office, 6 Waterloo Place, S.W.

County of London. — Horton Asylum, Epsom, Surrey. — Epileptic Colony, Ewell, Surrey,—Medical Superintendent of the Epileptic Colony, Ewell, Surrey. Salary £600 a year, with an unfurnished house. Applications to H. F. Keene, Clerk to the Asylums' Committee, London Asylums' Committee Office, 6 Waterloo Place, S.W.

Newport Borough Asylum, Caerleon, Mon.—Assistant Medical Officer. Salary £150 per annum, with board, apartments, and attendance. Applications to the Medical Superintendent.

Royal Mineral Water Hospital, Bath.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry. Applications to the Secretary.

Loughborough and District General Hospital and Dispensary.—Resident House Surgeon. Salary £100 a year, with furnished rooms, attendance, board, and washing. Applications to Thos. J. Webb, Secretary.

Manchester Royal Infirmary.—Director of the Clinical Laboratory. Salary £100 per annum. Application to Walter G. Carnt, General Superintendent and Secretary, Manchester Royal Infirmary.

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary £150 per annum, all found. Application to the Medical Superintendent.

Great Northern Central Hospital, Holloway Road, N.—Casualty Officer. Salary £100 per annum. Applications to L. H. Glenton-Kerr, Secretary.

Eastern Dispensary, Leman Street, Whitechapel, E.—Resident Medical Officer. Salary £120 per annum, with furnished residence, coals, and attendance. Applications to George W. Lisley, Secretary, 66 Great Prescot Street, E.

West Riding County Council.—Scalebor Park (Private Asylum) Burley-in-Wharfedale.—Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, &c. Applications to the Physician Superintendent.

Appointments.

BENNETT, H. G., M.R.C.S., L.R.C.P.Lond., House Physician to Out-patients at St. Thomas's Hospital.

BUTLER, G. G., M.R.C.S., L.R.C.P.Lond., to the Ear Department at St. Thomas's Hospital.

CASSIDY, M. A., M.B., B.C.Cantab., Resident House Physician at St. Thomas's Hospital.

COX, R. J. H., M.B., B.S.Lond., Resident House Surgeon at St. Thomas's Hospital.

DICKSON, A. N., M.R.C.S., L.R.C.P.Lond., Resident House Physician at St. Thomas's Hospital.

DIXON, WILLIAM JOHN, M.B., B.S.Madras, L.R.C.P.Lond., M.R.C.S., Medical Officer for the Templecombe District, by the Wincanton (Somerset) Board of Guardians.

DREW, J. H., M.B., B.S.Lond., Junior Casualty Officer at St. Thomas's Hospital.

DUNKLEY, E. V., M.B., B.S.Lond., House Physician to Out-patients at St. Thomas's Hospital.

EYRE, C. R. B., M.R.C.S., L.R.C.P.Lond., Senior Obstetric House Physician at St. Thomas's Hospital.

FRANKLIN, C. L., M.B., Ch.B.Vict., Junior House Surgeon at the Oldham Infirmary.

GAMLEN, R. L., M.R.C.S., L.R.C.P.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

GOTELEE, H. E., M.R.C.S., L.R.C.P.Lond., Senior Ophthalmic House Surgeon at St. Thomas's Hospital.

HEWETT, F. S., M.R.C.S., L.R.C.P.Lond., Resident House Surgeon at St. Thomas's Hospital.

HOOKER, A. W., M.B., B.S.Lond., Senior Casualty Officer at St. Thomas's Hospital.

HOWARTH, W. G., M.B., B.C.Cantab., Resident House Surgeon at St. Thomas's Hospital.

HOWITT, A. B., M.B., B.C.Cantab., Resident House Surgeon at St. Thomas's Hospital.

HUGGINS, G. M., M.R.C.S., L.R.C.P.Lond., to the Skin Department at St. Thomas's Hospital.

JUBB, ARCHIBALD, M.D.Glasg., Extra Assistant Physician to the Glasgow Royal Infirmary.

MACDONALD, S. G., M.B., B.C.Cantab., House Surgeon to Out-patients at St. Thomas's Hospital.

NIGHTINGALE, H. J., M.R.C.S., L.R.C.P.Lond., to the Children's Surgical Department at St. Thomas's Hospital.

PAGE, C. M., M.B., B.S.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

PHILPOT, H. A., M.R.C.S., L.R.C.P., House Physician to Out-patients at St. Thomas's Hospital.

READ, H. W., M.R.C.S., L.R.C.P.Lond., to the Dental Department at St. Thomas's Hospital.

SANKEY, W. O., M.B., B.S.Lond., Resident House Physician at St. Thomas's Hospital.

SQUIRES, H. C., M.B., B.Ch.Oxon., Resident House Physician at St. Thomas's Hospital.

SUHR, A. C. H., M.R.C.S., L.R.C.P.Lond., Junior Obstetric House Physician at St. Thomas's Hospital.

TREVES, F. B., M.R.C.S., L.R.C.P.Lond., to the Throat Department at St. Thomas's Hospital.

WALKER, S. L., M.R.C.S., L.R.C.P.Lond., to the Skin Department at St. Thomas's Hospital.

WALLACE, J., M.R.C.S., L.R.C.P.Lond., to the Throat Department at St. Thomas's Hospital.

WARD, W. C. A., M.R.C.S., L.R.C.P.Lond., Junior Opthalmic House Surgeon at St. Thomas's Hospital.

WHITEHEAD, C. E., M.R.C.S., L.R.C.P.Lond., House Physician to Out-patients at St. Thomas's Hospital.

WHITEHOUSE, H. B., M.B., B.S.Lond., House Surgeon to Out-patients at St. Thomas's Hospital.

Births.

KELLY.—On Dec. 14th, at 26 Blythswood Square, Glasgow, the wife of A. Brown Kelly, M.D., of a son.

LLOYD.—On Dec. 14th, at 6 Victoria Place, Haverfordwest, the wife of Perceval A. Lloyd, F.R.C.S.Eng., of a daughter.

Marriages.

DODGSON—GOOD.—On Dec. 8th, at Lyndhurst Road Church, Hampstead, W. Dodgson, M.D., of Southwaite, Carlisle, eldest surviving son of the late Dr. Dodgson and Mrs. Dodgson, Derwent House, Cockermouth, to Annie Florence, second daughter of Henry Good, Esq., of Alvaston, Arkwright Road, Hampstead.

GROUND—MACBETH.—On Nov. 14th, at St. Mary's, Johannesburg, Arthur Edward, eldest son of Edward Ground, B.A., M.D.Cantab., Maidstone, to Marjorie, youngest daughter of the late Major John Macbeth, 42nd Highlanders (Black Watch).

LAMBERT—ANDERSON On Dec. 14th, at the Cathedral, Singapore, Stephen George, youngest son of the late Richard Lambert, of Putney, and formerly of Roehampton, to Ethelwyn, only daughter of the late William Anderson, F.R.C.S., of London and Walton-on-the-Hill.

Death.

SYKES.—On Dec. 16th, at Westfields, East Grinstead, Walter John Sykes, M.D., F.I.C., in his 65th year.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIII. WEDNESDAY, DECEMBER 26, 1906. No. 26

NOTES AND COMMENTS.

Wanted—A Big Man.

The amount of annoyance and delay caused to medical men by being obliged to kick their heels about police-courts while trumpery cases are being disposed of, is exasperating in the extreme. Would that all magistrates were like Mr. Fordham. At the North London Police Court the other day when a medical man entered the witness-box, Mr. Fordham said he had noticed him in court all the morning, but did not know he was a doctor. He had a very strong opinion about keeping medical men from their practices longer than was absolutely necessary, and he had given strict orders that no doctor should be summoned till 11.30 a.m. at the earliest. He then inquired who was responsible, and was told a sub-divisional inspector, to which he replied that he wanted a bigger man than that to see his orders carried out. He then went through all the big men in the police service, and finally decided on the biggest, namely, the Chief Commissioner, and to him he wrote saying that he ought to issue an order that doctors were to be inconvenienced as little as possible in giving police-court evidence. This is a real grievance that Mr. Fordham has put his finger on, and he deserves the thanks of the profession for so manfully taking up the cudgels on their behalf.

London Meat Inspection.

A SPECIAL report on meat inspection in the City of London has been presented by Dr. Collingridge to the Sanitary Committee of the Common Council, in which he admits that under prevailing conditions it is useless to try to discover disease in the carcases at the Central Markets; all that can be attempted is to find out and seize unsound and decomposed meat. As there are no public abattoirs, it is impossible at present to inspect the organs of animals slaughtered, and so evidence of disease is rarely obtainable. But even as things are, Dr. Collingridge's staff is too small to cope with the work it has to do, for there are only five inspectors to look after the 1,352 tons of meat daily sent to the Central markets—a ridiculously disproportionate number. Moreover, it seems that the more carefully inspection is carried out, the more bad meat is discovered, for nowadays three times as much bad meat is found as in 1891. Altogether things seem to stand in need of considerable reformation in the City, and as an enormous proportion of the food supply of the country passes through its confines, it is a matter for some anxiety that greater care cannot be exercised by the responsible authorities.

Mrs. Osler, æt. 100.

There is a little irony, albeit of a pleasant order, in the fact that Mrs. Osler, the mother of the Regius Professor of Medicine at Oxford, should just have celebrated her hundredth birthday. To the man in the street her distinguished son is principally known as an ogre who would "euthanase" all people at sixty, and the fact that his own mother should have achieved the patriarchal age she has just attained is not without a humorous aspect. There was a great gathering at Toronto to honour the occasion, Professor Osler, various other children, grandchildren, great-grandchildren, and a host of friends. Naturally a reason had to be assigned for the phenomenal longevity of the heroine, and the Regius Professor attributed it to the fact that she is "always joking." Care and worry it is that kill, not hard work, and not sustained exertion. "Laugh and grow fat" may be good philosophy, but laugh and live long is better. If we could all enjoy Mrs. Osler's even temperament and happy disposition, we might drink and smoke, and keep late hours with comparative impunity.

Death of a Cancer Cure.

The public activity of the Liverpool herbalists has been several times commented on in our columns. These scientific gentlemen, it may be remembered, are anxious to establish a herbalistic medical school and to undertake "research" into cancer. There is a charming naïveté about a letter which one of them has lately addressed to a Northern contemporary. It begins: "Sir,—You will no doubt be surprised to hear that Mrs. Cottam, the lady reported to have been cured of cancer, passed away on Monday at noon. I regret to have to communicate this news to you, but feel it my duty so to do, in view of the interest you took in the case and in the subsequent investigation. . . . A botanic practitioner who saw her on Sunday, when she had a serious relapse, diagnosed it as mercurial re-action, the result of continued taking of drugs. . . . I feel sure that if the case could have been taken in hand earlier, and without previous years of ill-health, and the continued taking of medicine and the operation, a different result would have occurred." We do not wish to make capital out of the death of a fellow-creature, but the facts speak sufficiently loudly for themselves.

LEADING ARTICLES.

A BONESETTER'S CHALLENGE.

THE practice of unqualified people in medical and surgical fields—alias quackery—is permitted by the State. There is accordingly nothing to prevent them gulling the public with catchpenny pretentions. This attitude on the part of the legislature is absolutely illogical. They say that the duly qualified medical practitioner must have previously undergone a long and arduous course of special training and have passed stringent examination tests as to the soundness of his knowledge. The declared aim of the Medical Acts relating to medical practice is to enable the public to distinguish qualified medical men. That definition of purpose connotes that the public should be protected against the harmful practices of those who, being medically unqualified, nevertheless pretend to special knowledge in medical matters. The consequence is that any ignorant person is able to set up as a cancer-curer, a nerve specialist, a "bone-setter," or what not, and to work an infinite amount of harm to His Majesty's lieges, while, as a rule, he fills his own pockets with sums that to the average qualified practitioner would exceed the dreams of avarice. Of all the crew of impudent pretenders to special knowledge the bone-setter strikes us as being *facile princeps*. A typical sample of his preposterous claims may be found in a notorious irregular practitioner named H. A. Barker. That gentleman, conscious, no doubt, of the value of advertisement, is given to issuing challenges to the medical profession to investigate his methods. Of course we are aware that in noticing his latest effusion we are playing into his hands, so far as the granting of a huge free advertisement is concerned. However, our opinion of Mr. Barker and his methods will be so freely expressed that he is welcome to any slight advantage that he may derive from the fact that his name has been mentioned in one of the medical journals for which he expresses so much contempt. The circular advertisement to which we refer is a diffusely-written pamphlet written in the form of "an open letter" to the President of the Royal College of Surgeons of London. There is a Napoleonic air about this document that is characteristic of Mr. Barker. His tactics are those of the resolute guerilla chieftain who not only invades the rich city, but attacks the Governor's residence. Not only does he declare war to the knife against the medical profession, but he challenges the titular head of surgery in the United Kingdom to mortal combat. The expression, "war to the knife" is perhaps hardly suitable in connection with this gentleman, for he claims the proud title of "bloodless" surgeon, and appears to have assumed the American name of "osteopath," which was lately covered with world-wide ridicule by Mark Twain. The letter begins with a handsome admission that it is the duty of the general Medical Council to guard the public "to the best of its ability from the intrusion of quackery and pretence"—a duty, by the way, that the Council refuses to recognise. At the same time, he claims it is their duty to examine into any well-certified means for the removal of suffering. In other words, the Council is to be called upon to examine all irregular plans of medical treatment—including Mr. Barker's—and if found to be of any service, to grant a kind of informal official recognition of the claims of each particular method so approved. Conversely, we presume, if found wanting the Council's condemnation would put an end to any particular method found wanting. He next makes much of the fact that the discovery of the circulation of the blood, and of various other scientific truths, was at first rejected by the medical profession. At the same time we can safely assert that sooner or later every great truth has found acceptance, and every great error has been rejected by medical men. Nothing has ever ultimately proved right, for example, that has been before the medical profession for so many years as "bone-setting." Medical science is ever on the look out for help from any quarter whatever, and is ready to test anything. The Rōntgen rays, for instance, came from non-medical sources, so did the germ theory of diseases. An analysis of Mr. Barker's claims to superior knowledge reveals the assumption of something in his methods and manipulations that he does not specify. That is a kind of cheap challenge that is easy to make and difficult to accept. He asserts in one place that he is able to replace knee-cartilages displaced at football, so that the player is able to return to the football field in a day or two or a week or two, as the case may be, "as efficient as ever." That is so unlike any ordinary surgical experience that we should refuse to accept it except upon actual demonstration of a sufficient number of cases accurately noted as to anatomical and clinical dates and results. The general tone of assertions that are advanced in place of argument and proof may be gathered from the following passage:—"On an overwhelming average the osteopath cures and 'the competent surgeon' fails to cure. His artificial aids and artificial muscles are ineffective where the application of an intelligent persuasive leverage brings the patient to his normal state." That is to say, Mr. Barker claims powers that have been denied to the long line of illustrious surgeons that have gradually advanced British surgery to its present pitch of perfection. Recently the advent of the Rōntgen rays has enabled the surgeon to make a far more exact diagnosis in many deep-seated injuries and diseases of bones and joints. It is, of course, open to the bone-setter to produce radiographic evidence as to the truth or otherwise of his assertions as to displacements and injuries of bone. Mr. Barker declares he wants no advertisement as he makes an income, and enjoys the confidence of his patients. A more scathing commentary on the worthlessness of the Medical Acts in the protection of the public against the wiles of quackery than this "open letter" it would be difficult to imagine.

A MIDWIVES BILL FOR IRELAND.

There is little doubt that at the present moment the subject of the restriction of the practice of unqualified midwives in Ireland and of the registration of duly qualified women is receiving considerable attention, and it is by no means improbable that the near future will see the production of a Government measure for effecting these objects. The necessity for some action of the kind has been made very evident, not only in order to improve the class of midwife attendant upon the poor in Ireland, but also to remove the present injustice to Irish trained nurses which has resulted from their non-inclusion in the English measure. Two courses are open to the Government: either a short Act can be passed extending the present Midwives' Act to Ireland, or a new Act can be passed for Ireland alone. To the former of these courses there are many and obvious objections, many of which will be patent to the readers of this journal. They may be briefly summed up by saying that the present Central Midwives Board has not shown itself suitable for the management of the business entrusted to it, and that there is no reason to think it would be more successful in managing additional business. Moreover, it has shown itself as a whole singularly ignorant of the qualifications of Irish nurses, and intolerant towards even the most celebrated Irish training institutions. We think that there would be few in Ireland who would consent to a proposal to place Irish midwives under the Board. It follows, then, that a fresh Act is necessary, and it may not be unprofitable to consider some pitfalls which must be avoided. The English Act has failed because in the first place it has constituted a Board in so loose a manner that its personnel is unbusinesslike, and because so many conflicting interests are represented that the vital questions at stake have often been lost sight of in undignified squabbles. We have no hesitation in saying that an Irish Board, if it is to command confidence and to work with success, must be constituted on entirely different lines, and must contain a majority of medical men. The conception that a Board of this kind can be satisfactorily worked if it is under the control of a lay majority has been proved to be fallacious. None but medical men can attach the necessary relative importance to details of training and to the different points in the control of midwives, and, though it is right that the Board should also contain lay members, it is essential that its majority should be members of the medical profession. Next to the constitution of the Board, great difficulty is sure to arise in framing the financial clauses. The English Act provides that under certain specified circumstances a midwife must summon medical aid, but it does not provide any means by which the medical man so summoned may be paid, in the case of indigent persons. This difficulty in Ireland will not lead to so much trouble as in England, because there in such cases the midwife is always entitled to summon the Dispensary Medical Officer. There are, however, other cases in which the patient may not be entitled to the attendance of the Dispensary Medical Officer, but in which her friends may be unwilling to pay for medical advice. In such cases, seeing that it is compulsory on the midwife to send for the medical man, and that though there is no legal compulsion there is strong moral compulsion on the latter to answer her summons, some provision should be made for his payment. Lastly, there is the necessity of avoiding so far as possible the creation of a class of inferior and untrained medical practitioner. This is a difficulty which is hard to overcome, and which will be successfully combated by the creation of a suitable Central Board rather than by clauses in the Act itself. In conclusion, we venture to express the hope that any wise action of the Government in this matter will meet with the support of the whole body of the profession in Ireland. There is no doubt that legislation is necessary in the interests of the sick poor, and though such legislation may inflict a slight amount of injury on the medical profession, the public spirit which has always actuated our body should lead us to support a necessary reform. In return, the least that can be asked of the creators of the Bill is that they will avoid amateurism, that in the drafting of the Bill they will be guided by the advice of those who are best able to give advice, and that the working of the Act will be entrusted to those who alone are competent to work it with success.

NOTES ON CURRENT TOPICS.

Saucepan and Appendix.

If it be unfashionable for people not to have had appendicitis, it is as least as unfashionable for medical men not to have a theory as to the causation of the malady. One medical man thinks it is due to frozen meat, another to red rubber corks in ginger-beer bottles, a third to the use of enamelled saucepans. The last view, which is new to us, was recently enunciated by Sir James Sawyer, before the Birmingham Medical Society, it appears, and we can only admire the courage of the physician who can take up such a position in the heart and centre of the iron manufacturing trade. Already the storm has burst, and *The Ironmonger* has been emptying the vials of its sarcasm on the devoted head of the originator of the theory. We cannot undertake to say that its reasoning is faulty if it at all correctly represents Sir James Sawyer's argument. The writer puts it thus: Appendicitis and the use of enamelled crockeryware came into vogue at the same time; the enamel is apt to become cracked and spicules are dislodged; such particles when introduced into the intestine are apt to set up inflammation. Therefore, appendicitis is caused by enamelled cooking ware. The only flaw in the argument is that none of these spicules have been demonstrated in the lesions. On the

same principle *The Ironmonger* is prepared to show that meat-choppers cause appendicitis. Apart from chaff, the theory that enamelled cooking vessels are the originators of appendicitis has a good deal to be said for it *primâ facie*, and it is well worth bearing in mind. The remarkable increase of appendicitis of recent years must be due to some active cause.

The Passing of Dowie.

THERE is always something pathetic in the break-up of a strong man, but in the case of the prophet Dowie the pathos ends there. There seems to be no doubt that he is now totally insane, and so enfeebled in health that his life cannot be much prolonged. His wife and son are said to have deserted him, his followers have seceded, and his debts amount to about a million pounds. The last scene of all this strange, eventful history is therefore less than simple nothingness, for the prophet is discredited and spurned. The stupendous fact remains that this extraordinary and erratic genius has been able to bamboozle hundreds of more or less educated people for thirteen years, to extract money from them for his schemes, and to make them his dupes spiritually and physically. The depth of credulity in human nature thus revealed is one that must never be lost sight of in taking any scheme into account; it may, indeed, safely be said that there are plenty of people in the world who will believe anything that is said to them. Already on the ruins of the Dowie edifice a successor is trying to raise up a little kingdom of his own. The new impostor is named Voliva, and he himself is suspected of mental weakness. But no doubt he will get adherents. It is not stated if he has taken up the curing business, but that is always a safe card to play.

Liability for Typhoid Infection.

OF late years there has been a marked tendency in the direction of attaching legal responsibility to the owners of insanitary premises. Lately a striking case of the kind, the report of which appeared in our news columns last week, was settled in the King's Bench Division. An action for £1,250 damages was brought by a lady against a medical man, the proprietor of a hydropathic establishment in the Midlands, under the following painful circumstances. The plaintiff with her two sons, who were attending Eton, paid a visit to the institution in question, where they unfortunately contracted enteric fever, and one of the boys died in consequence. The case was settled on payment of the amount claimed, but the plaintiff clearly stated that she agreed to that course only now that attention had been drawn to the dangers run by the public. On the other side it was stated that the defendant denied that he was personally responsible, and said that point would have to be determined by subsequent litigation. Of all diseases enteric fever is emphatically preventable, and it is to be hoped that the ultimate blame will be fastened on the right shoulders. A hydropathic establishment is the place where one would naturally expect an absolutely pure supply of water.

The Income Tax and the Medical Profession.

THE Report of the Select Committee on the Income Tax will, on the whole, give satisfaction to the professional classes. It does not, of course, go far enough to satisfy the more extreme, but, nevertheless, if its recommendations be carried out it will do much to lessen the burden on professional shoulders. For the first time in our economic history the principle for which we have contended—differentiation between earned and unearned incomes—is admitted. While this distinction may present difficulties of application in detail, the general idea is clear enough. Apart from this differentiation, the proposals are in the main on the line of extension of the existing abatements on small incomes. Thus, it is proposed to allow abatement on incomes up to £1,000 a year, instead of £700, as at present, and to impose an extra tax on incomes exceeding £5,000 a year. The differentiation as to "earned" and "unearned" is only to apply to incomes not exceeding £3,000. We cannot, of course, hope for an immediate translation of these suggestions into law, but it is satisfactory to have it established on the authority of a Select Committee that the changes for which we have contended are practicable, and there is no reason why some of them, at least, should not find their way into the next Budget.

Fortunes from Quack Medicines.

A NOTICEABLE feature about the quack medicine business is that of the most glaring and most successful enterprises the proprietors are generally Americans or Colonials. Although it may be comforting to reflect that home quackery is of comparatively small proportions when looked at in the light of American quackery, it is not reassuring to find that any dealer in patent medicines from abroad or the Colonies can command the advertisement columns of the British press if he comes with his money in his hand. Such, unfortunately, is the case. No deal is too glaring for most newspapers. During the last few weeks the wills of several large patent medicine directors have been published, and they bear eloquent testimony to the profits derivable from the trade. Thus Senator G. T. Fulford, proprietor of "Dr. Williams' Pink Pills for Pale People," left a fortune amounting to no less than £1,311,000, derived chiefly from that concern; Mr. Charles E. Fulford, of the "Bile Beans" Company, a comparatively new affair, left £67,187; and his colleague, Mr. E. A Gilbert, £31,252. Mr. Lyman Brown, of New York managing director of A. J. White, Ltd., the firm which trade in "Mother Seigel's Syrup," died at the Hotel Cecil last October, and his will shows property in the United Kingdom alone of £31,782, as to how much he had in America we have no information. Medical men who toil day in and

day out among the poor may be inclined to look enviously on these sums, piled up by the methods used by their proprietors, but the consciousness of having tried to alleviate sickness and pain will amply compensate. There are more precious things than gold in the world. *Nudus intravi, nudus exeo.*

Anti-Vivisection Meetings.

The pugnacity of the Anti-Vivisection Societies shows itself characteristically in internecine conflicts between themselves; indeed it is a question of policy whether they would not be better left alone to fight out their differences, as the result would probably be the same as in the case of the Kilkenny cats. There was an amusing instance of the harmony prevailing among the members of the "cause" in the holding of two meetings of protest, within a day or two of each other, by the British Union and the National Anti-Vivisection. The former got in the first thrust, and with Mr. Lupton in the chair protested against the one-sided constitution of the Royal Commission on Vivisection, "now conducting its inquiry behind closed doors." Mr. Coleridge's organisation, however, soon got in their counter, this time against the refusal of the Royal Commission on Vivisection to hold its meetings in public or to allow the National Anti-Vivisection Society to be represented by counsel. Translated into ordinary language, these protests mean (*a*) that both societies are disappointed at not being able to perform in public; and (*b*) that each has been unable to put up its protagonist in the character he (the protagonist) would like. The former grievance has had any semblance of reality taken out of it by the resolve of the Commissioners to publish periodical reports of the evidence, but this is regarded as a very inadequate concession; sensationalism needs to be served up hot, or not at all. The second grievance, that Dr. Hadwen was not put on the Commission as an "expert anti-vivisectionist," is a "bit thin"; we have yet to learn in what way Dr. Hadwen is an expert. On the other hand, that Mr. Coleridge should be disappointed in not appearing as "counsel" before the Commission is a "bit thick," considering his known partiality for legal proceedings. For ourselves, we can imagine that the public gaiety has lost much in not having had Dr. Hadwen to overrule Mr. Coleridge, or Mr. Coleridge to object to Dr. Hadwen's objections to his questions.

A "Cure" for Opium Smoking.

The absurdity of so-called "drink cures" must be of course apparent to educated medical men. To find a specific antidote to alcoholic craving is to seek for the philosopher's stone or any other phantom. In most cases the "drink cure" simply substitutes one form of nerve poison for another, usually in the shape of some narcotic principle. Incidentally by thus trading on human weakness and credulity the vendors of the "cure" pile up riches unto themselves in the fashion one is wont to associate with quick-witted and unscrupulous business methods. At times they carry on their trade under a semi-philanthropic guise, but a little investigation soon reveals the trail of the serpent in the enterprise. With this experience of the Western world in mind it is with much doubt and suspicion that we read of a "new cure for the slaves of the opium habit in Malaya." The anti-opium movement in Malay has come to resemble a religious revival in England or America. An anti-opium society has introduced a "cure" for the opium habit in the shape of the dried leaves of a wild plant taken as an infusion. There is the usual testimony of reformed victims of the vicious habit, and the interesting fact that the price of the leaves is ten dollars per picul. Verily, the love of money is the root of all evil.

British Homeopathic Association.

The fifth annual meeting of the British Homeopathic Association took place on December 12th at Lord Cawdor's house, and the annual report of its work was read by the Secretary. In this great stress was laid on the opposition of homeopaths to "vivisection," although "research work of considerable value" had been completed at their new laboratory. The "research" work which homeopaths delight in is, we believe, confined to the "proving" of drugs, a delightful process which varies directly as the disposition and predispositions of the provee. Without dwelling, however, on the value of these searching scientific tests, we may remark that these provings are not mere experiments on animals, but experiments on man, and that if it is bad to give animals, say, a hypodermic injection of strychnine and then under an anæsthetic take a blood-pressure tracing, it must be infinitely worse to give a man a thousandth of a minim of tincture of belladonna and see if he survives. For it must be remembered that the more a drug is divided the more potent, in Hahnemann's opinion does it become. It is entertaining to read, however, that the present-day use of serums, vaccines, and emulsions brings the rest of the profession nearer to homeopathy, though we will not, of course, "acknowledge" it, but in the crude form in which we know these preparations we are "likely to do more harm than good." We remember some time ago a homeopath claiming diphtheria antitoxin for their own, but we fail to see how that or any other serum or vaccine is to be obtained without "vivisection."

Claim for Fees.

If medical men are liable for damages for mistaken treatment, it seems to be only fair that patients should be similarly liable if they do not carry out proper treatment when prescribed, for their failure to get well is liable to discredit their medical attendant. This month in the Kidderminster County Court a practitioner, Dr. B. Addenbrooke, brought an action for six guineas against a patient. The latter had damaged a

finger, and Dr. Addenbrooke having found a tendon severed, skilfully re-united it, and told the patient to attend at his house immediately if the finger were painful. There was great pain in the finger subsequently, but the patient did not put in an appearance for four days, and the operation eventually turned out unsatisfactorily. He then refused to pay. The judge said that there had been no want of skill on the plaintiff's part, and that the unhappy result was due to the patient's neglect. He therefore, gave judgment for the full amount. The "no-cure no-pay" system has no place in medical contracts, and we are glad to see the fact so satisfactorily confirmed.

Antitoxic Cruelty to Animals.

LIKE many progressive journals, the *Tribune* is given to dalliance with the unorthodox in medicine. A delightful letter appeared recently in its columns over the signature "M.D.," who takes his text from Dr. Hadwen's recently-issued pamphlet—we had almost written "tirade"—on "The Antitoxic Treatment of Diphtheria." He begins by discussing, with temperate reasonableness, the statistics of the disease before and after the introduction of the preparation in question. He then scores his one point, namely, that the fall in the total mortality began practically in 1900, whereas it should have shown itself immediately upon the introduction of antitoxin in 1895 or 1896. There are obviously fallacies in the way of accepting his conclusion. Much more, for instance, has been learned about the preparation, the dose and the prophylactic and curative properties of antitoxin. Moreover, its use had not become by any means general in 1896, and the ordinary causes of the increase in the diphtheria wave were still at work. But when "M.D." comes to state his own views we find the Tartar strain disclosed with a vengeance. Antitoxin treatment, he says, is a passing fashion destined to be crushed out of existence in a few years. The system, he vows, is associated with "too much cruelty to animals," and, moreover, is a filthy system of treatment. In short, it would be hard to pack a short letter with more errors of apprehension and reasoning than that of "M.D." After all said and done, he admits the fall in 1900, and so gives his case away. As to the cruelty to "animals," does he mean to mankind (*i.e.*, by way of hypodermic injection) or to the lower animals—for man is an animal no less than a horse? Then as to serum treatment, why is it more "filthy" and cruel to extract the serum of the horse and inject it into the human circulation than it would be to kill a calf or a pig (often under circumstances of revolting pain and cruelty),and thereupon introduce a lower animal serum into the human economy by the more roundabout agency of the slaughter-house and the kitchen? Assuming him to be really a Doctor of Medicine, "M.D." belongs to the type of intellectually untrained practitioners who constitute the scanty handful of medical anti-vivisectionists.

A Police View of the Infectivity of Consumption.

Of all the vexed questions that abound in public health that of the proper attitude with regard to the infectivity of tuberculosis is one of the most thorny. Is the malady to be scheduled among the infectious diseases, and thus brought within the machinery of notification, isolation and disinfection applied thereto? Or is it to be regarded in its present stage as a problem to be decided locally? At any rate, the fact remains that Government does not recognise that tuberculosis as such should be scheduled amongst the infectious diseases. That being so, it is not a little surprising to learn from a letter addressed to the editor of the *Manchester Courier*, and published on December 8th, that the writer, wishing to remove his mother who was suffering from advanced phthisis, to a sanatorium, was refused the police ambulance on the ground that tuberculosis was infectious. The applicant was then refused the use of an ambulance used for removing patients to the infectious hospitals, though why this was done it passes the mind of man to conjecture. The unfortunate man, who was thus bandied about between pillar and post, says that a high official advised him to use a cab. If that be the method of Manchester the sooner the ambulance system of the town is reorganised the better for all concerned. We imagine, however, the writer must have been labouring under a misapprehension with regard to the cab.

PERSONAL.

PERMISSION has been granted by the King for Dr. Kenneth Scott, F.R.C.S.Edin., to wear the Insignia of the Fourth Class of the Imperial Ottoman Order of the Osmanieh, lately conferred on him by the Khedive.

A NUMBER of distinguished Yorkshiremen, including Lord Halifax, Lord Allerton, Sir James Kitson, and Sir A. T. Lawson, are arranging to have the portraits of Professor Clifford Allbutt and Mr. Pridgin Teale painted by a well-known artist, in order to commemorate their great services to medical science in Leeds and the West Riding.

AN inquest was held at Brighton on December 17th on the body of Mr. Frederick Alfred Ficher, a retired medical man. Mr. Ficher met his death by falling from a third floor window. A verdict of "Accidental death" was returned.

AT the thirteenth annual dinner of the Royal Southern Hospital, Liverpool, earlier in the month, Dr. Macalister was in the chair. He was supported by Sir Alfred Jones, Mr. Rushton Parker, the Rector of Liverpool, and others.

AT a dinner in support of the Poplar Hospital for Accidents, held at the Holborn Restaurant on December 19th, Mr. Edward F. Turner took the chair. Sir John Hollams, Sir Edgar Speyer, Sir Henry White, the Hon. Sydney Holland, Mr. T. H. Openshaw, and other distinguished guests were present.

A Clinical Lecture

ON

THE DIFFERENTIAL DIAGNOSIS OF TYPHOID FEVER AND APPENDICITIS

By PROFESSOR F. LEJARS, M.D.,

Of the Faculty of Medicine of Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

Some ten years ago one of my medical colleagues, a most careful observer, sent to me for operation a young woman who had been admitted to hospital two days previously. For three days she had been suffering from pain in the abdomen, more particularly in the right iliac fossa. She presented some swelling of the belly, and her temperature was 101.5° F. with nausea and prostration. My colleague suspected appendicitis, calling for immediate operation, and as I was of the same opinion, I performed laparotomy, only to find a small, perfectly normal appendix, which, all the same, I thought advisable to remove. The cæcum was distended and gurgly, and was red in places. The wound was closed, but the prostration, insomnia and diarrhœa continued, and she developed a well-marked typhoid fever, from which in due course she recovered.

I have never forgotten the lesson, and since then I have more than once found myself face to face with doubtful cases of the same kind in which we were called upon to make the differential diagnosis between typhoid fever and appendicitis. Here is another case in which this problem presented itself under circumstances that lend themselves to the discussion we have in hand. In this instance the balance of opinion was in favour of its being typhoid fever, the diagnosis being based on what appeared good and sufficient reasons, yet the examination of the blood and the subsequent course proved it to be a case of appendicitis. A youth, æt. 20, was seized suddenly on September 27th with abdominal pain and colic without any particular localisation. There was diarrhœa, anorexia, and general discomfort. Three days later the pain became more acute and there was vomiting. On October 1st the pain became still more severe, and now it was referred more particularly to the right iliac fossa. On the following day the patient was brought into my wards. He was extremely prostrated with stupor, and had a pale anxious facies. He passed from six to eight yellow stools in the twenty-four hours, the belly was distended, and tender all over, but more so in the right iliac fossa. Temperature 100.5° F., pulse 65, regular. No change occurred during the next day or two. Examination of the blood showed: red corpuscles 3,600,000, leucocytes 19,000. Sero-diagnosis was negative. Some resistance was felt over the right iliac fossa; the diarrhœa and insomnia persisted. Matters remained about the same until the 8th, though the diarrhœa subsided somewhat. The iliac pain was very pronounced, the temperature oscillated between 100.5° and 101° F. On the 10th the blood examination gave, 3,900,000 red and 28,000 white corpuscles, the pulse remained slow (64) and the general appearance was disquieting.

We were prepared to operate, but the absence of well-marked signs in the iliac fossa induced us to postpone the intervention, and the patient slowly recovered.

I shall discuss later on the assistance to be derived from the examination of the blood, but for the moment I wish to call attention to the extraordinary similarity between the symptoms of this abnormal appendicitis, and those of typhoid fever. Our view was that it was a case of acute enterocolitis with appendicitis, but for some days it was extremely difficult to form an opinion. Such cases are by no means rare, and they have on various occasions led to the abdomen being opened in typhoid fever, and on the other hand, we have been induced to withhold our intervention in cases of appendicitis until it was too late. This being so, such cases deserve our best attention.

It seems to happen more frequently that appendicitis is diagnosed when the patient is really suffering from typhoid fever than the converse. Nevertheless, in two instances we have diagnosed typhoid fever in patients sent to us for "appendicitis," and which turned out to be typhoid fever. But surgeons are not always equally fortunate. Kelly and Hurdon report several striking examples of this. A nurse, æt. 23, was seized with excruciating pain in the abdomen while on duty. The abdomen was found to be distended and resistant, there was nausea and then vomiting, and the temperature ran up to 106° F. They diagnosed acute perforating appendicitis, and operated, but it turned out to be typhoid, from which she died. In another case a boy, æt. 8, suffered for two days from pain in the right iliac fossa with distension and muscular rigidity, and a temperature of 104° F. He was operated on for appendicitis, but the appendix was healthy, and it again turned out to be typhoid, fortunately followed by recovery. A third case, with a less fortunate ending, was that of a medical man, who for two years had been suffering from attacks of colic thought to be appendicular; ultimately the pain in the right iliac fossa became so severe as to necessitate his taking to his bed. Matters went on thus for some weeks, when the pain became localised exclusively in the right iliac fossa, and was diagnosed to be due to appendicitis. The belly, however, was flat and soft. He was operated on, the appendix was found adherent to the cæcum, but in no wise diseased. Six days later internal hæmorrhage set in, rose-coloured spots were detected, and the spleen could be felt. He died on the twelfth day. It would be easy to multiply similar observations.

Although it is less common for an appendicitis to be mistaken for typhoid fever than the converse, the consequences of the error are even more to be feared should the error persist. Box and Wallace (*Lancet*, June 6th, 1903) record the case of a man,

æt. 50, who was suddenly seized with pain in the right iliac fossa; the temperature went up, the pulse was 120, with intermittent delirium at night and slight diarrhœa. During the third week there were three copious hæmorrhages with bright red blood, and typhoid fever was diagnosed, although no rose-coloured spots were seen and the sero-reaction was negative. Death occurred on the twenty-first day. *Post mortem* they found an abscess in the right iliac fossa around the appendix, but no trace of typhoid ulceration.

From what precedes, it will be seen that the conditions under which the mistakes were made were very dissimilar. There were acute cases, with sudden onset, high fever and rapid pulse, a bad general state from the beginning, abdominal distension, an ill-defined pain in the right iliac fossa, which might be either typhoid fever or appendicitis. Generally, however, the onset was more gradual, corresponding fairly well to the period of invasion of enteric fever. In these doubtful forms what led to the diagnosis of appendi itis was the prominence of the iliac pain and the partial subsidence of the other signs. The weight of opinion was in favour of typhoid when there was diarrhœa, headache, and stupor. In typical cases, of course, such an error could only arise in consequence of inadequate examination, but in the mixed cases under consideration certain signs are wanting, and those present can only be rightly interpreted by an attentive study in their totality, none of them viewed separately being pathognomonic.

In appendicitis the onset is usually more acute and severe. The pain sets in suddenly and forthwith increases in intensity. Nausea and vomiting usher in the scene, and the temperature goes up. Even in cases which, later, become obscure or in which unexpected accidents supervene, it is rare for this history not to be obtained. The pain may be moderate, it may not be just where we should expect to find it, it may be lower down, peri-umbilical, or sub-hepatic, but it is quite exceptional for it not soon to become localised in one spot, usually at or in the immediate neighbourhood of McBurney's point. It is not only sensitive to pressure, but the pain is there always. The wall is tense, rigid, and the least pressure accentuates the muscular resistance. We may get iliac tenderness at the onset of typhoid, and sometimes this tenderness assumes the character of genuine pain, but it is more diffuse, less fixed, it is specially marked on pressure, and when it is sought for the wall remains supple. Gurgling, of course, signifies little or nothing.

We know that diarrhœa is by no means rare in appendicitis, and that it is especially common in the very grave septic cases. It is consequently a grave element of prognosis. But diarrhœa from the onset usually indicates the crisis of entero-colitis, in the course of, or following which, the appendicitis has developed. It may be very copious during the first few days, and this is unusual in typhoid, in which the diarrhœa as a rule only sets in after a preliminary period of constipation. We meet with every variety, however, and no hard and fast rule can be laid down, but the significance of this inaugural diarrhœa must not be lost sight of.

The insomnia, headache and mental depression may of course be merely due to the fever, and we must not forget that these symptoms occasionally assume a very grave aspect, closely simulating, in fact, the symptoms of typhoid.

We must be on the look-out for the other signs, which, however, may be lacking—epistaxis, rose-coloured spots, which anyhow do not make their appearance until the eighth day; and the sero-reaction which, if positive, settles the question, but if negative merely leaves it open.

Albuminuria is commoner and more marked in typhoid fever than appendicitis, and the presence of albumen early in the case is not without significance. Then comes the blood examination, and its value is extreme. In non-complicated typhoid fever hypoleucocytosis is the rule; in appendicitis, especially when tending to suppuration, we find hyperleucocytosis. The existence of this hyperleucocytosis is a fact of the greatest importance in assisting us to arrive at a correct diagnosis. In my case it oscillated between 19,000 and 28,000, and this result, in the ascertained absence of any pleuro-pulmonary mischief or other focus of inflammation, militated strongly in favour of appendicitis. Of course, numerous examinations of the blood will be necessary for this information to possess its maximum value, but when the hyperleucocytosis persists and increases *pari passu* with the local mischief, there remains no room for doubt. Even after the first examination our views underwent a change, and sundry phenomena, previously ill-understood, were seen in a new light. The importance of this line of research at an early stage cannot be too strongly insisted upon, but we must bear in mind that hyperleucocytosis may be absent in certain cases of hyperseptic appendicitis, and that certain inflammatory complications of typhoid fever, apart from appendicitis, may, on the other hand, give rise thereto. We must therefore be guided by the symptoms as a whole, but in this whole the hæmatological data occupy a conspicuous place.

It may happen that typhoid fever and appendicitis set in together in such wise that their symptomatology becomes mixed; indeed, this association is by no means rare, especially in children. It may of course be objected that in this event we are not dealing with appendicitis properly so-called, but rather with appendicular lesions of typhoid origin. The result in any case is to mask the symptoms of typhoid fever. It sometimes happens that in the course of an ordinary attack of typhoid fever during which at no time has attention been called to the appendix, grave accidents may supervene presenting all the appearances of typhoid perforation, but due in fact to an overlooked appendicitis. On the other hand, we may recall the cases of "ambulatory" typhoid in which peritonitis suddenly supervenes. This is diagnosed as acute appendicitis, and laparotomy is performed, only to find a typhoid perforation—if indeed anything at all is discovered, for the perforation may be very minute, and situated high up in the small intestine.

In the last-named contingencies, the practical question of the proper course to follow can be stated without hesitation. We must act, and act at once, however obscure the diagnosis.

In the cases first dealt with—those in which we have to ask ourselves whether the case is one of typhoid fever or appendicitis—it is quite otherwise. Unquestionably when the accidents are not alarming, when there is no threatened generalisation, and when, in spite of the diarrhœa and the general

appearances, the pulse is of normal rapidity and is full and regular, we can take our time, and usually in a few days, with close observation, the problem will solve itself. It cannot be denied that the doctrine of immediate intervention in appendicitis has tended to increase the number of instances in which a healthy appendix has been removed from a typhoid patient in the initial stage. But there are cases in which the symptoms are so acute that we dare not delay, consequently, when in doubt, and in presence of pressing symptoms, it behoves us to operate, diagnosis or no diagnosis.

Note.—*A Clinical Lecture by a well-known teacher appears in each number of this journal.*

ORIGINAL PAPERS.

NOTES ON A CASE OF HYSTERECTOMY FOR FIBROMYOMA UNDER SPINAL ANALGESIA.

By J. H. SWANTON, M.D., M.Ch., R.U.I., M.R.C.P.Lond.
Obstetric Physician to the Kensington General Hospita. &cl,

The patient from whom this tumour was removed is forty-four years of age, and complained of pain in the left side, bearing down on walking, increasing frequency of micturition both by night as well as by day, and occasional attacks of diarrhœa. She had enteric fever when sixteen and small-pox some years later.

Menstruation began at fifteen; the periods being regular, every twenty-eight days and lasting seven days. Occasionally the discharge returned after two days' apparent cessation and lasted one day. The amount lost was excessive. There was severe pain one week before appearance of menses. Since marriage the pain has disappeared but the amount has not diminished. Intermenstrual leucorrhœa came on soon after marriage, and there was some uterine displacement for which a pessary had been worn.

She has been pregnant three times, and the youngest child is eight years of age. Her labours were severe, and she dates her present illness from the birth of the second child, when she had a flooding and was ill for three months. The abdominal wall moved equally on respiration, and a hard mass was felt above the pubes extending upwards and to the left for six centimetres. Some mucous polypi projected from the cervix; the fundus was directed forwards. An irregular hard mass occupied the upper part of the pouch of Douglas, which was continuous with that felt through the abdominal wall. The uterine cavity measured eight centimetres. She refused to have the tumour removed, and as an alternative curettage was performed. Within three months menorrhagia returned, and was treated medicinally with ergotine, adrenalin, cotarnine hydrochloride, and phthalate, hydrastin, each in turn affording temporary relief.

The symptoms increased in severity, hæmorrhage became greater, pain in left side now radiated down the left thigh and leg. Insomnia was constant.

In September last I found her anæmic from hæmorrhage, suffering from intense pain and insomnia. A presystolic murmur was heard over base of heart inside the nipple line. The uterine tumour now extended seventeen centimetres above the symphysis and pressed on rectum and sacral plexus posteriorly. Some mucous polypi protruded from the cervix.

Operation was advised, and patient was admitted to hospital early in October last. After consultation with the staff it was agreed that a general anæsthetic would probably end fatally, so it was decided to operate under spinal analgesia by the injection of one of the new amino-alcohols known as novocain.

The operation took place on October 14th. The patient sat on the operation table in a flexed position while a trocar and canula were passed into the space between the laminæ of the third and fourth lumbar vertebræ on the left side for about two centimetres. On withdrawing the trocar a few drops of cerebrospinal fluid escaped. At 11.14 a.m. three cubic centimetres of a 5 per cent. isotonic solution of .15 gramme of novocain and .00325 gramme of suprarenin borate was injected into the spinal canal. The patient then lay down and the pulse was observed to be 120.

At 11.28 *i.e.* fourteen minutes after injection, patient complained of pricking in her toes, but sensation was unimpaired and voluntary movement continued. This paræsthesia passed off in five minutes, and her pulse was 134. Another injection of 3 c.c. was given on right side at 11.40, and in four minutes sensation and movement of lower limbs were impaired. At 11.50, six minutes later, patient said her toes were "pricking something awful." At 11.57 the paræsthesia passed off and was followed by complete loss of sensation and voluntary movement in the lower extremities.

The pelvis was now raised into the Trendelenberg position, and in five minutes analgesia had extended to the level of the umbilicus. At 12.2 p.m. a median abdominal incision was made eight centimetres long which had to be enlarged, after peritoneum was opened, to deliver the tumour from the pelvis. The tumour was held up while the cervix was defined by thumb and forefinger of the left hand. The posterior vaginal wall was incised longitudinally for four centimetres over its attachment to the cervix, which was then seized by a strong vulsellum forceps and drawn upwards and backwards through the incision. The vaginal attachment was then cut through by scissors curved on the flat. The tumour was drawn upwards and forwards and separated from the bladder anteriorly, when the utero-vesical pouch was opened, leaving the tumour attached only by the broad ligaments.

These were now clamped through the infundibulopelvic ligament on each side down to the opening in the vaginal roof. The tumour and adnexa were then removed, the ligaments being tied in sections and vessels ligatured separately. The raw edges of peritoneum were united by a continuous suture of catgut.

During the preceding manipulations it was observed that at 12.14 p.m., twelve minutes after the operation commenced, the pulse was 96 and of low tension. At 12.20 a few mouthfuls of watery fluid were vomited, when pulse tension increased. At 12.22 patient complained of thirst, and took three mouthfuls of hot water and brandy. The tumour was removed at 12.30, and in five minutes afterwards the pulse was 96.

At 12.45 the patient had a further draught of water and brandy, the pulse was 116 and tension was increasing. There was no change in the facial aspect from the commencement of the operation.

When the vessels in the broad ligament were seized preliminary to ligature the patient complained of a twisting dragging pain, which also came on whenever the parietal layer of the peritoneum was drawn forward.

At 1 o'clock peristalsis began, the pulse became rapid and irregular, but within ten minutes was less frequent, full and regular.

Some nausea and straining came on, the intestines became distended so that suturing was delayed and interfered with. The patient was then put under anæthesia by A.C.E. mixture and the operation completed.

The subsequent convalescence was complicated by nausea, pain referred to umbilicus, and paralytic ileus, which disappeared after several turpentine enemata had been administered.

The patient was discharged on the 24th day and progress continues satisfactory.

The tumour weighs 1587.57 grammes, or 3½lb., and involves the posterior wall of the uterus, apparently commencing interstitially and soon involving the endometrium. The uterus is extended considerably and the cavity much enlarged. The tumour is a fibromyoma.

Spinal analgesia is likely to prove useful in gynæco-

logical and obstetrical cases where prompt operative interference is required, but owing to the existence of shock a general anæsthetic is contraindicated.

A CAUSE OF FATAL COLLAPSE AFTER PROLONGED ABDOMINAL OPERATIONS.

By R. H. HODGSON, M.D.DURH., M.R.C.S.ENG.

THE British Gynæcological Society is more concerned in abdominal operations and has done more to perfect the technique of abdominal surgery than any other society in London, but since there is no end to learning, may I suggest that the relative importance of the selection of an anæsthetic in long operations upon the abdomen is, I fear, too often overlooked, and the choice left to the anæsthetist, with the result that many cases of fatal collapse are erroneously assigned to the length of the operation rather than the unsuitable anæsthetic. No one would wish to place the cause of a fatal termination of an operation upon the shoulders of the anæsthetist, nor would any operator desire to share the feeling of sorrow, at the loss of his patient, by division of responsibility. The operator is, and must be, the unfortunate one upon whom rests the weight of the disaster. It, therefore, behoves him to give careful consideration to the question which is the most suitable anæsthetic, in each case, for the safety of the patient, bearing in mind that no one, before opening the abdomen, can say with certainty, that the operation will not be a long one. I feel fairly confident that if sufficient statistics were available, we should find that, comparatively, many more deaths followed long operations upon the abdomen when the anæsthetic was ether than when it was chloroform, and I am constrained to think so for many reasons which I hope to be able to lay before you in a sufficiently lucid manner to cause many of my hearers, if doubtful of my views, to at least give the subject their serious consideration.

If we carefully observe the action of Alcohol, Ether and Choloroform upon the human body when living and when upon the *post-mortem* table, we will find that alcohol and ether have actions so similar that it will not be necessary to differentiate between them. The difference between chloroform and ether, however, is very great upon the body. On observing the living heart we find that its frequency of action is increased by ether and decreased by chloroform. That its power is increased by ether and decreased by chloroform. That the volume of blood passing through its cavities is decreased by ether and increased by chloroform. That when death takes place from ether the heart ceases in diastole, and when from chloroform in systole. Few exceptions indeed can be found to these states, and they can mostly be accounted for by efforts to resuscitate the patient, such as artificial respiration and inversion of the body.

Generally speaking, we may say that ether expends and chloroform husbands nerve energy. That ether causes capillary contraction and chloroform capillary dilatation, and that both cause death by congestion and consequent functional insufficiency of the lungs, may be explained by the assumption that ether contracting the capillaries and thereby inducing increased heart action, capillary congestion results, and that chloroform by relaxing the capillaries depletes the heart which, becoming gradually slower, weaker, and more empty, permits stasis of blood in the lungs. If the administration of chloroform be farther continued, the lungs, overcharged with poisoned blood, cease to work, and the patient dies with an empty heart, that organ having made its last stroke after the lungs have ceased to respire. This chloroform congestion of the lungs is of the nature of hypostasis. But the congestion of the lungs under ether is a capillary engorgement under pressure, with the result that the patient dies of enervated heart action brought about by an endeavour on its part to force the circulation. Hence we find in addition to the capillary congestion an exudation around the capillaries and into the air vesicles and lungs generally.

It is this exudation which is the most difficult obstacle to restoration in threatened death from ether anæsthesia, and the one from which the patient is liable to collapse many hours after having been returned to bed and having recovered consciousness.

From the foregoing remarks we may assume that both chloroform and ether produce anæsthesia by impeding the due elimination by the lungs of certain poisonous substances. Whether those substances be gases wholly or in part it is difficult to say, but it is their accumulation which is the narcotising agent. Neither chloroform nor ether *per se* could cause that condition to supervene in the quantities necessary to produce anæsthesia unless aided by something else. Chloroform and ether are the collectors of the narcotising agents.

Dr. F. W. Hewett says: "Junker's inhaler does not necessarily rob chloroform of its dangers." This lends weight to my view that the danger clearly must arise from something other than chloroform, since the administration by this apparatus needs but such a small quantity of chloroform to produce anæsthesia. Taken by the mouth in like quantities, these drugs have little effect. They thus differ from hydrocyanic acid, which when inhaled appears capable of destroying life unaided and in far too short a time to admit of death from suffocation. Theoretically when the capillaries of the lungs are becoming stagnated by ether contraction, and the heart consequently full, chloroform should be the antidote by relaxing the capillaries and thus relieving the heart, but by the time that ether has gone so far, the heart is on the verge of collapse from exhaustion due to its poisoned blood supply and its struggle to force the circulation. By the smaller amount of blood passing through the capillaries during ether administration and the cooling nature of that drug, the body becomes markedly cold, and, indeed, has a frozen feel in those who are unfortunately about to succumb to its administration. Dr. F. W. Hewett, when speaking of people who suffer from dyspnœa when not under an anæsthetic, says: "Generally speaking, the presence of even moderate dyspnœa calls for chloroform."

Here he recognises that chloroform interferes less with the aeration of blood in the lungs than does ether. Chloroform appears to ease the dyspnœa by allowing a freer flow of blood through the proper channels.

Further, the same author says: "In advanced heart disease ether should be avoided." Here he evidently considers that ether puts stress upon the enfeebled heart, exciting it beyond endurance in its effort to force the blood through the contracted capillaries. We do not want, in an engorged lung, contracted capillaries to prevent the free circulation.

Whilst upon the capillary irritation and contraction, I hope that I may be excused for remarking in a gynæcological society that this raises in my mind some doubt as to the advisability of administering oxygen in pneumonia. In years past it was not unusual to keep a patient under chloroform for as long as two days in the hope of curing an aneurism. If any one has made the attempt to keep a patient under ether for two days it would be as well not to enquire the result of that operation.

If we examine for ourselves those cases of deaths occurring during chloroform administration with which we are personally acquainted, I think we shall find that each has been accompanied by one at least of the following circumstances—the administrator was inexperienced or in a hurry to get the patient under, the surgeon was in a hurry to begin or get away, or a friend was keeping up a conversation in the anæsthetist's ear. A chloroformist told me that through the many thousands of major operations in which he had given chloroform he had never had a death. I believe that man was both truthful and had a good memory, and I never saw his eye off his patient whilst he was administering chloroform. Anæsthetists abound, but chloroformists of high perfection in its administration are few, and the constant laudation of the ever springing up of supposed safe and new anæsthetics only tends to perpetuate the desire to avoid the use of an anæsthetic believed to be most

dangerous. The great objection to chloroform appears to be the fact that if once the heart is allowed to become completely empty, then recovery from impending death is almost hopeless. Threatened death from ether narcosis does give time to attempt the restoration of the patient, but how many recover after unequivocal signs of heart failure, under this drug, is a question which must be left for statistics to settle, if they can show differentiation between death from true surgical shock and the inability of the heart to maintain the circulation whilst the absorption of the exudation surrounding the capillaries and invading the air vesicles is proceeding. Ether is supposed to render complete anæsthesia of the nerves of sensation.

The fatal collapse of a patient after a long and difficult operation which has at last succeeded surgically, is one of the most trying and disheartening events in a surgeon's life; but this is of minor importance, since the surgeon will probably outlive it, and with the exception of perhaps the addition of a few more grey hairs to his head, will show no outward sign of the grief it has caused him. The patient, however, has gone, and although in some, if not many, of the cases requiring serious operations, this termination may, so far as the patient is concerned, be the best for him individually, yet there may be those left behind deprived of the one most dear to them and often the one whose loss means their worldly downfall. If, therefore, this paper may have seemed somewhat irrelevant in a society devoted almost wholly to surgical work, I trust that I may be excused for thus occupying your time on the ground which I have endeavoured to show that the anæsthesia and the operation should be inseparable from the operator.

NOTES FROM THE FRAUENKLINIKS OF HEIDELBERG AND FREIBURG. (a)

By H. MACNAUGHTON-JONES, M.D.

PART I.

"Bene diagnoscit, bene curat." This is the aphoristic motto that all who enter Professor Krönig's operating theatre may read. Surely none could be more aptly chosen, and no words could speak more eloquently to the gynæcologist. Great technical skill and manipulative dexterity are the handmaids of a particular technique, but justification for the risk involved in the carrying out of any predetermined method and the responsibility incurred in advising operative interference must in both cases depend on accurate diagnosis—*early* diagnosis, for assuredly the great blot on the page of progress in gynæcological practice is the casual, procrastinating habits of us doctors. With all our talk, writings, and discussions, pathological displays and operative triumphs, are we getting nearer the supreme aim of every surgeon—early recognition of the abnormal, early detection of signs that throw light on symptoms, early acceptance of the grave responsibility cast upon us by that first appeal made to us for relief of symptoms, it matters not how slight those symptoms may be? It were well that those terms (too often the cloak for carelessness, indifference, or ignorance!)—"neuroses," "neurotic," "neurasthenia," "hysterical," were dead phrases to most of us. Pain would not then be ignored, a discharge trifled with, a locomotor difficulty assigned to gout or rheumatism, a pregnancy confounded with a cystoma, or *vice versa*; nor should we read of revelations following the discovery of a loose kidney, or death in a few days from a fulminating appendicitis. We should not hear so often of "inoperable carcinoma," of ruptured pyo-salpinx, of fatal collapse from ectopic gestation, of two to three hours operative procedures, ending in early collapse or sepsis.

But assuredly the saddest of all the consequences of neglect of early diagnosis is that which follows in the wake of cancer and cancerous infection. While we are still groping in the dark for a cure, waiting on pathological research, and following the *ignis fatuus* of some advertised therapeutical boom, we let slip the time for applying the only cure we as yet know of—viz., early and free operation. If this society, now in its dying hours, sent out no other message, trumpet-tongued, to the profession, or left no other legacy as the outcome of its accumulated experiences than this: "Diagnose cancer early," it would have justified its existence, and the initiators of it, dead or living, would have earned our gratitude

Medullary Anæsthesia.—Before referring to the kliniks of Heidelberg and Freiburg, I desire to touch on the question of spinal anæsthesia, inasmuch as it was in regard to what I saw of this new movement in operative gynæcology that I was most interested. There can be no doubt that the man deserving the greatest credit for the introduction of this method of securing narcosis is Bier, who, in 1899, first employed cocaine for this purpose, unaware and quite independent of Corning's treatment of spinal affections with intradural injections of the same drug. Bier (like Simpson and Duncan in the case of chloroform) experimented on himself and his assistant Hildebrandt, and both experienced several of the unpleasant after-effects. Results were not encouraging, but Tuffier, in France, followed in 1900 with 250 operations, of which 142 were laparotomies. Of 1708 cases reported by Hahn in 1901, eight had died, and Morton, of San Francisco, reported 673 operations under cocaine. In 1904 Bier made the next great advance in the addition of the antidotal adrenalin, and in substituting stovain (first employed by Sonnenburg) for cocaine. Doenitz was associated with Bier in his work.

Since 1904 a host of workers have been giving their experiences. These have turned mainly on the relative value of the drugs used—leucaine, tropacocaine, stovain and novocain, the last three being those commonly used; on the advantages and disadvantages of this anæsthetisation as compared with general anæsthesia and chloroform; on the dangers associated with it, and how to avoid them; on the precautions to be taken in, and the best method of administration of, the anæsthetic; on the employment of it for operations above the level of the umbilicus; on its suitability in particular cases; on the disadvantages of retention of consciousness; on the combination of scopolamin and morphia narcosis with the use of either stovain or novocain, as introduced by Kronig. A few words on each of these questions may not be amiss.

First, as to the relation of the value of the drugs employed. Leucaine (Jedlickal and Mayer) has been abandoned (Engelmann). Tropacocaine is still employed by Doenitz for operations above the level of the umbilicus. He reports on it most favourably in combination with scopolamin and morphia as accessory narcotics. The patient is not conscious, and the pelvis need not necessarily be elevated. Of the three, tropacocaine seems to Doederlein to be very far the best. He thinks also the toxic effects are less after it.

Schroeter reported a failure of thirteen out of eighty-six administrations of stovain; one case was resuscitated from collapse by cardiac massage and artificial respiration, but in that there had been re-injection of the spinal fluid several times. He also uses novocain. Professor Leyer considers that medullary anæsthesia should not be used save where infiltration anæsthesia or perineural cannot be carried out, or where general narcosis is contra-indicated. In two out of nine cases there was serious collapse from novocain.

Veit (Halle) prefers stovain, a smaller quantity being required to secure anæsthesia. Sonnenburg now uses novocain and suprarenin. In 603 cases (114 stovain and 135 stovain-adrenalin) there were five deaths. Neumann (Berlin) uses both stovain and novocain with suprarenin. Koenig (Altona) prefers stovain-Billon to the stovain-Riedel and to novocain.

Franz (Jena) uses novocain and suprarenin and morphine-scopolamin narcosis. He has had 180 operations without a death, or any threatening symptoms.

This is sufficient to show that there is not complete unanimity as to the best of these three, and it would appear that there is not much to choose as between

(a) Read at the British Gynæcological Society, on Dec. 13th, 1906.

the stovain and novocain, though preference seems now to be given to the latter.

As to the precautions to be taken in the administration, these are included in my ref rences to the kliniks. Purity of drug is essential, and it is questionable if it should not be as fresh as it is possible to have it.

Dangers Associated with the Practice of Spinal Anæsthesia.—The principal of these are arrest of respiration from involvement of the medulla, and the motor nerves; collapse immediately during or after operation; spinal paralysis; sepsis. All of these have been causes of death. Care in carrying out the strictest aseptic details, deliberation in selection of the spot for puncture, slowness of injection, not too rapid elevation of the pelvis, the combination of the scopolamin and morphia narcoses, are most necessary.

There can be no question that the risk is greater when the punctures are made higher in the cord than the umbilical level. We have not, however, to say to this here.

What, then, are the advantages claimed for this method over that of chloroform and general anæsthesia by other means?

They may be briefly and categorically stated thus:—Chloroform is avoided in cases in which general anæsthesia is contra-indicated, in cardiac diseases and in arterio-sclerotic states; the possibility of deferred death from chloroform in prolonged administration is not to be feared, the action of the abdominal muscles in abdominal operations is not encountered, the frequent post-operative effects of chloroform and ether are absent.

What, now, are the disadvantages? Firstly

The Perception of the Operation.—Surgeons are by no means unanimous as to the benefit or the contrary of retained consciousness during a long abdominal operation. Certain disadvantages will strike you at once.

The Chance of Vomiting.—This has often taken place during, and has continued after, operation, with all the drugs used. It is not so common now, owing possibly to better administration, and in no single case did I see it occur at either klinik.

Movement of the Bowel.—This, in operations on the perineum, or plastic vaginal operations, makes the administration somewhat risky in such cases. I did not see it occur, though I witnessed several plastic operations.

Insufficient Narcosis.—This may be due to dispersion of the drug and dilution in the spinal canal, with failure in the anæsthesia. Strong traction of the pelvic viscera tends to interfere with it.

Risk of Collapse.—This appears beyond doubt to be a risk that must be estimated in these cases. Possibly an injection of strychnine and atropine, given half an hour before the operation, may prevent this. The addition of the adrenalin solution has materially lessened it.

Respiratory Paralysis.—These cases have been very few comparatively. Too rapid injection and raising of the pelvis, or injury to the anterior roots, may predispose to it.

Injury to the Motor Nerves during Injection.—This will be avoided by care in the puncturing.

Headache.—This follows in a certain number of cases under all the drugs, and with every precaution.

Sepsis and Impurity of Drugs.—These drawbacks have to be met by strictest asepsis, and the guarantee of the chemists. This is but a very remote danger.

Just a word on the scopolamin, morphine, and chloroform anæsthesia. Scopolamin is, as you know identical with hyoscine. In carrying out this method the scopolamin—1-64th to 1-200th of a grain combined with ¼ to ½ grain of morphia is injected subcutaneously the night before the operation, and repeated an hour before it takes place. Chloroform or ether is then given in the quantity required. Take he following case as an example:—

A patient, æt. 70, was carried into my study after a long railway journey, in a collapsed condition. In her state it was impossible to make an examination. I ascertained, however, that there was a fœtid growth protruding from the vagina, and I drew off five pints of urine from the bladder. The right leg was affected with neuritis, for which she had been in bed six weeks. By nutrient enemata and injections of strychnine, she was kept going for three days. On the night of the third day she had a scopolamin and morphia injection. On the following morning, two hours before the operation, she had another. One hour before the operation a strychnine and atropine injection was given (a plan I have always adopted in any serious abdominal case since reading the experiments of Prof. Schaeffer and Mr. Scharlieb). I removed the growth, which evidently sprang from the anterior vaginal wall in front of the trigone and then invaded the cellular tissue, spreading high up into the left fornix. Both sides were freely cauterised. It has proved to be a carcinoma.

Mr. Scharlieb, who gave the patient chloroform, informs me she was put under with rather less than half a drachm of a 10 per cent. alcohol, and 90 per cent. chloroform mixture, and kept under with about 3 drachms of pure chloroform, with a Vernon-Harcourt regulator; mostly between 0.4 and 0.6 of chloroform. She did not suffer after the operation, and passed a perfectly quiet day and night without any sickness.

THE OUT-PATIENTS' ROOM.

PADDINGTON GREEN CHILDREN'S HOSPITAL.

Case of Dorsal Caries.

By A. EDMUNDS, M.S., F.R.C.S.

AMONGST the out-patients was the case of a female child, æt. 5, who had been under treatment for the past eighteen months. When she first presented herself at the hospital she exhibited the characteristic symptoms of spinal tuberculosis in the mid-dorsal region. In her particular case the pain was not very acute, but there was a well-marked deformity, and there was definite rigidity. The characteristic deformity could be easily elicited by attempting to flex the spine, thus bringing into relief the acute break in the curve at the seat of the disease. Rigidity could be best demonstrated, Mr. Edmunds pointed out, by placing three fingers on the tips of three adjacent spinous processes; keeping each finger carefully in place over the corresponding spinous processes, movements of the spinous processes upon each other would be readily manifested by the separation or approximation of the fingers. The child showed no sign of abscess and no sign of paralysis. It was, therefore, a typical case of spinal caries in a comparatively early and therefore hopeful condition. The number of appliances, he said, which have been invented for spinal caries was enormous, and there were few without drawbacks. His own routine treatment for spinal caries in very young children consists in keeping the child flat upon a hard mattress; he instructs the parents of the child to procure a board about three feet long by about eighteen inches wide; upon this are placed two or three layers of dressmaker's cotton wool, and the whole covered by a blanket. The child is kept in a flannel nightgown, which is

divided down the back, so that it can be tucked under the sides of the child without disturbing the infant; shoulder-straps are fixed to keep the child's shoulders on the board; blankets and rugs can be wrapped round the child and the board. The little patient can remain quite comfortably on this apparatus as long as necessary—usually for about twelve months. It can be washed with a minimum of disturbance, and can be carried about the house or taken out of doors without danger to its spine. As regards the excretions, any small dish, for example a small pie-dish, can be used. The whole of this apparatus can be manufactured for about 1s. 6d., and it has the advantage over the more elaborate forms of apparatus that, being made by the parents, it can also be kept in order by them. It is a very common disappointment, he thought, to find an expensive piece of apparatus put on wrongly, broken and bent, so that it is perfectly useless. The method he had just described he illustrated in the out-patient room by means of models. This board is not so good for children over four years old, and for these he prefers a Phelp's box. This most excellent appliance is sometimes regarded with suspicion, owing probably to the faulty patterns which are sometimes made. The points to be attended to are: (1) The box must be long enough to allow for growing—about six inches longer than the patient; (2) the divided portion of the box must be so arranged as to keep the child's legs abducted; (3) the piece of wood which comes up on the inner side of the leg is generally made too broad; it should be planed down, so that where it reaches the opening round the perineum it is only about half an inch wide. Unless this is done it is impossble to bandage the child firmly in. The box should be lined with thin firm cushions made of American cloth, which should be encased in washing covers. The child can be taken out once a week and washed on a bed. These cases soon learn to keep their whole back so rigid that the disturbance produced by lifting the child out of the box does no harm. After the child has been kept in the box for a sufficient time, Mr. Edmunds was in the habit of ordering the appliance which the patient under observation was now wearing—namely, a tailor brace. The principle of this last was that there was a firm pelvic belt, kept in position by perineal straps; to this are rivetted a pair of steel bars, which pass up one on each side of the spine, following its curves. These steel bars terminate above the middle of the clavicles about on a level with the posterior border of the sterno-mastoids, and bear at their end an arrangement of straps by means of which the shoulders are held back to the supports, transferring the weight of the trunk and the muscular pull from the diseased bodies of the vertebræ to the sound neural arches. An abdominal belt can be added to steady the whole. With these three types of apparatus one can, he considered, manage most cases of spinal caries. While the all-important rest for the vertebral bodies is procured, one should not neglect hygienic measures. Fresh air is as valuable for these as for other tuberculous conditions. As regards internal drugs, he was in the habit of always giving cod-liver oil unless it disagreed with the patient.

OPERATING THEATRES.

ROYAL FREE HOSPITAL.

Strangulation by Meckel's Diverticulum.—Mr. Wilmott Evans operated on a man, æt. 24, who had been admitted suffering from acute abdominal pain. The patient had always been well, and had never had any similar attack before. On the morning of the day of admission he had suddenly felt an acute pain in the region of the umbilicus. The pain steadily grew worse, and about four hours after its commencement he began to vomit; the vomiting continued until the time of admission. The bowels had been acting normally, and an ordinary motion occurred soon after the commencement of the pain, but for the last few hours he had not passed even any flatus. On examination he was seen to be a well-built and well-nourished man, his pulse was 92, and his temperature normal. The abdomen was distended, and it was noticed that the distension was not uniform, the middle portion of the abdomen being especially prominent, while the flanks were flattened. Palpation revealed nothing, and on percussion the abdomen was everywhere resonant, excepting for the normal dulness over the liver. He complained of pain a little to the right of and below the umbilicus. His vomiting persisted, but there was nothing specially noticeable about the matters vomited. Acute intestinal obstruction was diagnosed, and it was suggested that the obstruction was probably caused by some peritoneal band. The patient was anæsthetised, and, the abdomen having been cleansed and a catheter passed to empty the bladder, a three-inch incision was made in the middle line between the umbilicus and the pubes. On dividing the peritoneum some highly distended small intestine presented itself, and also towards the right side was visible some collapsed bowel; the collapsed bowel, which was evidently ileum near the ileo-cæcal valve, was followed upwards until it was found to join a piece of distended gut, and at the place of union a narrow tense band constricted the bowel. At this stage it could not be seen where this band was attached; the band was carefully divided, a pair of pressure forceps being placed on each side of the point of division. As soon as the band was cut through, gas passed from the distended portion to that which had been collapsed, and the bowel became uniform in appearance, the situation of the constriction being, however, still visible as a slightly depressed line. Next the attachments of the portions of the constricting band were examined; one was found to pass upwards to the umbilicus and the other to pass downwards to a part of the small intestine a few inches above the place where the constriction had occurred; this was some three feet from the ileo-cæcal valve. The lower part of the constricting band was dilated and formed a diverticulum from the bowel. It was clear, Mr. Evans pointed out, that this was a Meckel's diverticulum, which had been attached to the umbilicus, and had been in part obliterated. The portions of the band were removed, the diverticulum was dissected off, the edges were turned in, and the wound in the bowel closed by Lembert's sutures. The abdomen was closed in the ordinary way. Mr. Evans said that the sudden onset of the abdominal pain, the vomiting and the distension of the abdomen, combined with the inability to pass flatus, all pointed to acute obstruction of the band, also that this obstruction was in the small intestine was shown by two facts:—(1) the sudden onset, which was hardly ever seen in obstruction of the large intestine, though occasionally in volvulus of the sigmoid flexure the symptoms may suddenly become acute; (2) the shape of the distended abdomen showed that only the small intestine was dilated, and that the large intestine was empty. In such a condition of things immediate operation was the only possible treatment. With regard to the operation itself, little, he thought, could be said. When, on opening the abdomen, portions of dilated and compressed bowel were visible, it was clear that the site of constriction must be between them. It was much easier, he said,

to manipulate collapsed bowel; therefore, as a rule, it was better to follow the collapsed bowel upwards to the point of obstruction. In this case, the obstruction had not continued long enough to make it at all probable that any permanent harm had been done to the wall of the intestine, and therefore that part needed no treatment. It was considered advisable, he remarked, to remove the remains of the constricting band, in case at a later period strangulation should occur.

The patient made an uninterrupted recovery.

OPERATION FOR THE CURE OF A FÆCAL FISTULA.—Mr. T. P. LEGG operated on a young woman, æt. about 25, for the cure of a fæcal fistula in the right groin; the fistula had been present for many years. She gave a history of having had a lump which was tender and painful in the upper and inner part of Scarpa's triangle. She had been to another hospital, where a knife had been put into the swelling, and a fæcal discharge had continued ever since. When admitted to the Royal Free Hospital, there was a fæcal fistula in the upper part of Scarpa's triangle, discharging a great deal of greenish semi-solid, very irritating fluid, so that the whole of the lower part of the abdomen and the right thigh as low as the knee were excoriated and eczematous. Her general health was good, she had not lost much flesh, and there was nothing abnormal to feel in the right iliac fossa, or in any other part of the abdomen. Rectal and vaginal examinations were also negative. She was kept in bed for some time, and means taken to improve the local condition of the skin before proceeding to operate. At the operation a curved incision was made over the lower part of the right rectus muscle, and a bougie passed through the fistulous opening to serve as guide to the opening into the intestine with which the sinus communicated. On opening the peritoneal cavity no adhesions were found except where the fistula opened into the bowel; the sinus was cut across and the loop of intestine brought up into the incision. The opening was situated on the convex border of the bowel. The part of the intestine beyond the fistulous opening was somewhat contracted, and there was a well-marked spur, which had served to direct the intestinal contents to the surface. The edges of the aperture were refreshed, and then sewn up by two layers of sutures; the sinus was scraped with a sharp spoon, and a drainage tube placed in it. The abdominal incision was completely closed after the intestine had been replaced. Mr. Legg said that this fistula was probably the result of a strangulated hernia having been mistaken for a mass of inflamed glands; most likely the hernia had become considerably inflamed, and there being no impulse on coughing it was easy to see how without care such a mistake could be made: hence the importance of exercising great care in opening all inflamed swellings in the groin, especially in women, in whom the source of the bubo may not be as obvious as it generally is in men. The situation of this fistulous opening could be diagnosed, he thought, as being in the lower part of the small intestine, because in the first place the patient's general health had remained so good, and secondly by the character of the discharge: in fæcal fistula high up in the small intestine the patient as a rule emaciates very rapidly. With regard to the discharge, it was semi-solid, and not so irritating to the skin as when it comes from the upper part of the small intestine. The chief danger during the operation, he pointed out, was septic infection; this can be reduced to a minimum by adopting the plan of opening the abdomen as in this case, and by carefully plugging the fistulous opening. The difficulties of the operation, he considered, were:—First to find the affected coil, and secondly to separate the adhesions without further damaging the wall of the gut. It was interesting to notice, he remarked, that although this condition had been going on for so long, there were few adhesions, the explanation being that the fistula was the result of a strangulated hernia, and not due to any inflammatory state, such as tuberculous peritonitis, or chronic appendicitis. The method of closure of the intestinal aperture adopted in this case was, he said, satisfactory if the hole is comparatively small and in the long axis of the bowel wall; stenosis under these conditions is not likely to subsequently occur. A larger aperture, especially if the intestinal wall itself was rotten or friable, demanded excision of the involved portion, and end-to-end union of the resected loop of bowel.

The patient made an uninterrupted recovery, and left the hospital three weeks after operation. It was interesting to observe, Mr. Legg subsequently pointed out, how quickly the skin recovered when the fistulous opening was closed; the sinus, too, healed up rapidly.

TRANSACTIONS OF SOCIETIES.

BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, DECEMBER 13TH, 1906.

The President, MR. BOWREMAN JESSETT, F.R.C.S., in the Chair.

MR. FURNEAUX JORDAN made a further communication on the specimens shown at the last meeting. The uterine fibroid had been carefully examined by the pathologist in Birmingham, and stated to be an œdematous fibroid.

SPECIMENS.

Dr. SWANTON showed a uterus removed by abdominal hysterectomy for fibroma under spinal analgesia. (which will be found on page 693).

Mr. CHARLES RYALL showed

A UTERUS REMOVED UNDER SPINAL ANALGESIA FOR HYPERPLASTIC ENDOMETRITIS.

The patient was aged thirty, and was suffering from menorrhagia. She had been in several hospitals for the same trouble, and had been curetted. On examination the uterus was found to be large and patulous, almost admitting the tip of the index finger. After preliminary preparation abdominal hysterectomy was carried out on November 7th. She was injected with one and three-quarter ampulla of 5 per cent. novocain solution, and analgesia was established in about ten minutes. The whole operation took exactly forty-one minutes. During the operation the patient did not complain of any actual pain, but she stated she felt something being pulled when he seized the uterus and drew it up to the abdominal wound. She was nervous and upset, and had some vomiting, causing the intestines to bulge into the wound, so that he was compelled to desist until the attack passed off. He could not say at the moment how long the analgesia lasted, but she made an uninterrupted recovery. He did not know enough about spinal analgesia to pass an opinion on it at present. His first experience of it was in Paris one and a half years ago, when he saw a patient have abdominal hysterectomy performed under stovain. At that time he was not very favourably impressed with it. The patient's general condition in the present case was bad, and his brother, Mr. Canny Ryall, suggested that he should do the operation under novocain. So far everything in connection with the matter had been exceedingly satisfactory. He thought there were a certain number of cases in which spinal analgesia was preferable. Another set of suitable cases were those where there

was some pathological pulmonary condition, such as pneumonia. Another class was that in which there were serious lesions of the heart. So far he was not prepared to say that he considered it a suitable routine method, but he considered it most useful. Shock was said to be diminished by using spinal analgesia. Shock was much better understood now than formerly, particularly in abdominal surgery.

Dr. HODGSON read a paper on

A CAUSE OF FATAL COLLAPSE AFTER PROLONGED ABDOMINAL OPERATIONS.

(which will be found on page 694).

Mr. SPANTON dissented from the view that the surgeon should choose the anæsthetic. He thought that after the surgeon had stated the nature of the operation and the length of time it would be likely to take, the choice of the anæsthetic should be left to the anæsthetist. He agreed that the surgeon would be responsible for a fatality if the operation were unduly prolonged, as that added to the shock, and also it might be necessary for the surgeon to suggest a change in the anæsthetic.

Mr. FURNEAUX JORDAN endorsed the remarks of Mr. Spanton that the surgeon should not be held responsible for the anæsthetic used. Legally the anæsthetist was responsible, not the surgeon. He doubted whether there were many cases of fatal collapse in abdominal operations. He took it that if a patient died suddenly after an operation, in the vast majority of cases it would be found that there had been hæmorrhage, or other cause for the death apart from shock or collapse. With regard to the choice of an anæsthetic, for many years the Birmingham Hospital for Women had used an anæsthetic which was extremely simple and easy to give, and gave excellent results. It had only one drawback, and that was anæsthesia was produced slowly, as eight or nine minutes were required. It was a mixture of one of chloroform to two of ether, in a Clover's inhaler without the bag, and given so as to exclude the air underneath the face-piece. The patient went under anæsthesia easily. Little sickness had been noticed after its administration, and it could be given for any length of time. Personally he had found it invaluable. He would very much regret to see a return to chloroform as an anæsthetic. He believed chloroform should not be used as an anæsthetic unless there were special indications for it.

Mr. CHARLES RYALL said that the surgeon was responsible for the anæsthetist, and the anæsthetist for the form of anæsthetic he employed. If death happened under chloroform it did so at once, whereas ether was responsible for certain complications of a pulmonary character, which occurred at a remote period after the operation. Fatal collapse always followed prolonged operations, but with improved technique one could get over that to a large extent. There was frequently more waste of time at operations than there need be. He believed the risk was not in an overdose of the anæsthetic, but in giving too little of it. By adopting every means of saving time in operations, and taking care that the patient was deeply anæsthetised, shock would be greatly diminished. One great cause of shock was handling of the intestines and other parts.

Mr. STANMORE BISHOP pointed out that the administration of anæsthetics was now a separate and expert art. A man was either an anæsthetist or he was a surgeon, and he held very strongly that neither man should interfere with the other—that the surgeon should not consider it his duty, after he had chosen a fully qualified and thoroughly reliable anæsthetist, to dictate to him as to his choice of anæsthetic. With regard to the question of shock following prolonged operations, he thought that rapidity of operating had become to a certain extent a fetish, which men were inclined to magnify unnecessarily.

Dr. HODGSON, in reply, questioned whether it was right to leave the choice of the anæsthetic to the anæsthetist, as the public employed a surgeon to do the operation and save the patient, and they did not anticipate that the surgeon was going to hand over the safety of that patient to a stranger. He held that the surgeon was morally responsible, whatever took place. There was no doubt that unfavourable symptoms occurred some time after an operation, for which he considered the surgeon responsible. With regard to the administration of chloroform *versus* ether, when ether was brought into use thirty years ago it was supposed that nobody would die as a result of its administration, and it was largely used at St. Bartholomew's Hospital. But since that time ether had been less employed, and now was not used there more than 250 times in the year. Doubts had been expressed whether many people did actually die from shock or collapse following operation. Chloroform was safe if one had competent men to administer it.

Mr. H. MACNAUGHTON-JONES read

NOTES FROM THE WOMEN'S CLINICS OF HEIDELBERG AND FREIBURG,

with illustrations by the epidiascope shown by Dr. Macnaughton-Jones and Mr. Overy (which will be found on page 695).

The PRESIDENT said that the society had had placed before it most interesting papers and specimens from Dr. Spanton, Dr. Hodgson, and Mr. Charles Ryall, on which he invited discussion.

Mr. CANNY RYALL said that his experience in the use of spinal analgesia was founded upon some thirty or forty cases, and the conclusion he arrived at was that he would never think of using a general anæsthetic for an operation below the level of the diaphragm if he had "Novocain" at hand. He had been interested to hear the description of the method adopted abroad; it was not the best. He found the first necessity was to withdraw from the spinal canal such a quantity of fluid as it was proposed to inject of the spinal analgesic. He took care not to mix his novocain with spinal fluid. In any operation involving the lower limb he gave 5 c.c. of the 2 per cent. solution of novocain and suprarenin. For an abdominal operation, 10 c.c. of the same strength, after removing 10 c.c. of cerebro-spinal fluid. He believed the whole success of the procedure was due to the removal of cerebro-spinal fluid. None of the patients up to the present time had died, and two of the cases were quite cured. Three weeks ago he removed the rectum and part of the sigmoid flexure after excising the coccyx and part of the sacrum, and used spinal analgesia, and the operation lasted under an hour, and when the wife and daughter were brought in to interview the patient the man had a smile on his face, so that his relatives scarcely believed that the operation had been done. So that in such a very formidable operation as Kraske's, there was an absence of shock, though altogether the patient was under the influence of the drug six hours. He had gone on from that day to the present without a bad symptom. So there must be something good in spinal analgesia. In addition, he had performed appendicectomies, many operations on the lower limb and radical cures of hernia, and up to the present with no ill effect. The fact which impressed him most particularly was the absence of shock. He had not used stovain. One reason for that was that if applied to mucous membranes it was apt to cause sloughing. He had applied novocain and closely watched its effects on the mucous membrane of the mouth and nose, and in urethral work and cystoscopic work, but he had not seen any such effects following its use. He had nothing but praise for novocain, and he would not think of using a general anæsthetic after the experience he had had with novocain. Patients who had it rarely suffered from sickness afterwards, and a few only had headache.

Mr. SPANTON said he had no experience of spinal analgesia himself, but one approached a new matter of that kind with an open mind. It had been the fate of all anæsthetics when first introduced to encounter a considerable amount of opposition. Still it seemed necessary to proceed with considerable care in such a matter, because he gathered that five deaths had occurred from anæsthesia so induced in the cases abroad at one of the clinics referred to, and that there were two deaths in 380 cases at Freiburg, which was a high percentage of mortality. They were told also that in most of the cases which occurred there,

vomiting took place. One of the drawbacks of general anæsthetics in abdominal operations was vomiting. When one considered that only 500 cases had been done at Freiburg and there had been two deaths, there must not be too much haste in adopting it. He had not the same dread of general anæsthetics as some, because he had seen many instances very similar to the one which was quoted where the condition of the patient was so extreme that the anæsthetist did not care to give any anæsthetic whatever.

Dr. HERBERT SCHARLIEB spoke as a mere anæsthetist, and said stovain, novocain, etc., had come to stop, and it was useless and unscientific to take up an attitude of hostility towards them. They are very excellent and eminently suitable drugs to be employed in certain cases, but they had the decided disadvantage of being only analgesics, not anæsthetics. The patients lose the sensation of pain, but they are aware of every touch. This must be a decided disadvantage to the operator when the patient is highly nervous or imaginative. Such a patient might move at an awkward moment, and certainly might experience a good deal of mental shock. One of the objections to a general anæsthetic is its lethality immediate or remote—on the table or after the operation is well over. He held that the lethality of chloroform (at any rate during its administration) was wholly due to improper dosage. Chloroform being so safe (when properly administered and adequately guarded), he doubted the other methods of local or spinal anæsthesia—at any rate in our present state of knowledge—being more valuable. In any case the present death-rate of chloroform is estimated as about 1 in 4,000, whereas up to now that of stovain and novocain is appreciably much higher. In conclusion he urged that these drugs being new, and, so to speak, on their trial, they should avoid praising them too highly as absolutely safe, or condemning them too readily as too dangerous.

The PRESIDENT said that Mr. Canny Ryall brought about spinal analgesia in a patient of his for the operation of appendicectomy. She was under the influence of the anæsthesia in less than eight minutes from the commencement. He removed the appendix in a comparatively short time, and she was chatting the whole time, and seemed to take little or no notice of the operation itself. There were no bad symptoms afterwards, no vomiting or headache, and the patient made a natural recovery. With regard to his personal opinion, no doubt it took time to get used to new fashions. He preferred to get his patients under a general anæsthetic. Dr. Swanton went carefully into the condition of the pulse at various periods of the operation and of the anæsthesia, and he believed at one time it went as fast as 150 per minute. A question which arose was, was that caused by the anæsthetic, or by shock or nervous depression; or was it due to the operation itself?

Dr. GILES said, with reference to the subject of spinal analgesia, he thought all honour should be given to the pioneers of a method of treatment such as the present one, and Mr. Canny Ryall was to be congratulated in that he had picked up the subject for himself, and carried it so far towards a successful issue. The general mortality from general anæsthesia, such as ether anæsthesia, was something like 1 in 25,000; and although Dr. Hodgson attributed a good deal of serious shock after operations to general anæsthesia, he could not say that he altogether agreed. He thought that fatal shock after operations was generally due to operative and not anæsthetic conditions. But seeing the safety of the general practice of anæsthesia and the general satisfactoriness, some operators might be excused if they hesitated somewhat before adopting another plan. At present the mortality from spinal analgesia appeared to be a good deal higher. Whilst the new method had some advantages, it also had some disadvantages. But there was no doubt the only proper attitude to adopt was to preserve an absolutely open mind, and see how the results went; not discouraging the pioneers, but asking them, on the other hand, not to mind if their colleagues preferred to wait a while before using it.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD THURSDAY, DECEMBER 13TH, 1906.

The President, Mr. PRIESTLY SMITH, F.R.C.S., in the Chair.

MR. E. TREACHER COLLINS described the macroscopic and microscopic appearance of an

ADHESION OF A PERSISTENT PUPILLARY MEMBRANE TO THE CORNEA

in the eye of a cat, and compared these with four other recorded cases of a similar nature. It was suggested that they might be divided into three classes with the following characteristics: (1) A cicatrix of a perforating ulcer of the cornea, with the pupillary membrane attached to the scar (Wintersteiner). (2) A cornea in all respects normal, except for a defect in the endothelium on its posterior surface at the seat of attachment of the pupillary membrane (Collins, Ballantyne). (3) A cornea in all respects normal, except for an absence of Descemet's membrane and its lining endothelium at the position where the substantia propria and pupillary membrane become blended (Von Hippel). The case, the subject of this communication, came under the third heading. In class 1 the cause of the adhesion was undoubtedly inflammatory in origin. In the cases belonging to the other two classes there was an absence of all signs of past or present inflammatory changes, and in some of the eyes there were other congenital malformations which could not be inflammatory in origin. The balance of evidence in them would seem to be strongly in favour of the abnormality being due to an arrest of development.

In class 2 the arrest occurring in the differentiation of the mesoblastic tissue, posterior to the hyaline layer of Descemet's membrane, into endothelium and pupillary membrane. In class 3 the arrest occurring in the formation of a partition of the hyaline layer and the differentiation of the mesoblastic tissue between the lens and surface epithelium into two parts.

Messrs. L. V. CARGILL and S. MAYOU described a case of

FLAT SARCOMA OF THE CHOROID.

The patient was a man, æt. 61, who was first seen in August, 1904, complaining of failure of sight of the left eye. At the outer side of the macula was a patch looking like an area of choroido-retinitis. The retina had an œdematous appearance, and at the lower border of this area were some dark choroidal pigment spots, with other spots less pigmented. The patch was not definitely elevated, but there was a scotoma corresponding to it; the vision was $^{6}/_{24}$. The right eye was normal.

In spite of warning, the patient did not show himself for a year, and then the retina was partially detached, with much pigment along the border of the detachment. Vision was $^{6}/_{18}$. The use of Leber's transilluminator rendered the diagnosis of tumour certain.

The patient was not again seen until March, 1906, when he had secondary glaucoma. Tension +2, and vision P.L.

The eye was removed, and a funnel-shaped detachment of the retina was present. In the outer half of the globe there was a flat, darkly pigmented growth. In the region of the ora serrata it was raised and tended to spread in a ring-like manner. The optic nerve and sclera were not involved. The growth was strictly limited to the choroid, and was composed of spindle cells with no alveolar arrangement, and a few large chromatophores. Anteriorly it showed well-marked signs of degeneration necrosis; there were also some small hæmorrhages.

Dr. CECIL SHAW (Belfast) read notes of a case of

PERFORATING WOUND OF THE EYEBALL,

with complete destruction of the iris and retention of vision. The patient was an engine-driver, æt. 37, who was removing the tyre of a bicycle, when the wrench which he had inserted under the edge of the tyre slipped and flew out, striking the right eye, and cutting the cornea from edge to edge a little below the centre. The anterior chamber was filled with blood, and when after some days this cleared off, it was seen that the iris had completely disappeared, leaving the lens in place, but evidently injured at its lower edge, from

which a few opacities spread through its lower third. These showed no tendency to increase. The wrench was a particularly sharp and rough-edged one, and probably caught the iris and tore it out. All signs of irritation passed off in about a month, but some floating opacities remained in the vitreous. The man was able to return to his work in six weeks with vision $^{6}/_{18}$ and $^{6}/_{12}$ partly in the injured eye.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held December 7th, 1906.

Dr. Leonard Mark in the Chair.

Mr. Donald Armour read a paper on

Perforation in Typhoid Fever,

in which he stated that perforation was more common in men than in women, very rare in children, and the third week of the disease was the most frequent time. Out of 167 cases the perforation was situated in the ileum in 136, or 81.4 per cent.; in the large intestine in 20, or 12.9 per cent., in the vermiform appendix in 5, or less than 3 per cent. The symptoms on which most dependence could be placed were sudden acute pain in the abdomen, collapse, and an abrupt fall of temperature. Intestinal hæmorrhage and a steadily rising leucocytosis were danger signals. He dwelt on the great importance of early recognition of the symptoms, and the calling in of surgical aid. In suspected cases in which it was impossible to arrive at a diagnosis in other ways, a small exploratory incision under local anæsthesia should be made.

The use of opium was only justifiable after the diagnosis had been made. In operating two points should always be remembered. (1) That there may be more than one perforation present; (2) That it is necessary to examine the appendix before closing the abdomen.

Mr. McAdam Eccles agreed that an operation should be prepared for immediately the signs and symptoms of perforation were apparent, and alluded to the difficulty of diagnosing between perforating appendicitis, and perforations in enteric.

Mr. Paton thought that a Widal's reaction should always be taken as an aid to diagnosis.

Mr. F. G. Lloyd agreed that opium should be given after diagnosis so as to lessen shock, and to keep the patient in a better condition for the operation.

Dr. A. E. Russell also read a paper on the

Etiology of Uræmia.

The cerebral manifestations of uræmia were alone considered. The similarity between many of the symptoms of uræmia and those of conditions attended with increased intracranial tension was remarked upon. Indeed, uræmia had often been diagnosed erroneously as cerebral tumour. Conditions of increased intracranial tension were apt to be associated with an increase in the blood pressure. The meaning of this had been made clear by Harvey Cushing, who showed by experiments on animals that an increase of intracranial tension was associated with a gradual and corresponding rise in the peripheral blood pressure; within certain limits the blood pressure rose to a point above the intracranial tension. Without this compensatory rise in blood pressure the cerebral circulation would cease when the intracranial tension became equal to that of the blood pressure. Cushing had also shown that in cases of intracranial hæmorrhage associated with a high puels tension, the blood pressure fell to a most marked extent on trephining, and evacuating the blood. Similarly with cerebral tumour the general pressure symptoms were markedly relieved by operative measures designed to lower the intracranial tension; convulsions ceased, headache and vomiting were relieved, and optic neuritis subsided.

In uræmia a very similar group of symptoms was often to be seen, and inasmuch as the condition was then commonly associated with an increased blood pressure, it was permissible to enquire whether the explanation might not be the same, viz., that the intracranial tension was increased. That this is so was practically proved by the large number of cases which have been reported in which immediate and striking relief followed on lumbar puncture in uræmia, and it was to be noted that the relief was most marked when the cerebro-spinal fluid spurted out from the needle, *i.e.*, when the pressure within the spinal space was greatest. It was urged that in such cases lumbar puncture should be performed.

Mr. McAdam Eccles said that it was a physiological fact that the removal of cerebro-spinal fluid was followed by rapid resecretion of the liquid, and suggested the advisability of prolonged drainage in cases where simple puncture was ineffective.

Mr. Keetley, Mr. F. G. Lloyd and others took part in the discussion.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

President—Joseph M. Redmond, M.D., P.R.C.P.I.
Sectional Secretary—F. C. Purser, M.D., F.R.C.P.I.

Meeting held Friday, December 7th, 1906.

The President in the Chair.

OUR DEBT TO IRELAND IN THE STUDY OF THE CIRCULATION.

Dr. George A. Gibson (Edinburgh) read a paper on the above subject. He said that from his earliest days the heroes of medicine in Ireland had always been the objects of his worship. The first of the medical works produced by Ireland which had come into his possession was a copy of the first edition of Graves' immortal lectures; and he believed that for felicity of diction, breadth of view, and originality no other clinical lectures could be compared to them. Another Irish work of similar lucidity, greatness of view, and originality was "Stokes on the Heart." It was, he averred, the greatest book on the heart that had ever been published, and still stood absolutely without parallel. In that book Stokes coined the term "embryocardia" fifty years before it passed into currency, and he did more for the study of aneurism than any of his predecessors. Long before Oertel, Stokes had enunciated the advantages of exercise in the treatment of heart disease, and other methods of treatment which had slowly filtered into the minds of the medical profession since. Amongst numerous books and papers, all of great value, the speaker instanced the papers by Sir Dominick Corrigan on aortic disease as being epoch-making, little having since been added to the information contained in them. Amongst isolated papers upon cardiac disease perhaps the most valuable that had ever been published was one by the celebrated Adams, which appeared in the fourth volume of the "Dublin Hospital Reports." Many of his friends had been in the habit of attributing to John Hayden the information that when pericarditis followed on acute rheumatism the cause of the exudation, whether it was fibrinous or liquid, was that the heart was always in movement; but that had been expounded by Graves long before John Hayden. In looking through old files he had been struck with the fact that little had been written on angina pectoris, and he was inclined to hope that Ireland escaped that fell malady more than the sister islands. In other respects, Graves and Stokes were precursors of much now known. Somewhere in the thirties there was noticed a case of paralysis of the leg due to arterial obstruction—a forerunner of the views now enunciated as intermittent claudication. A host of Continental observers had studied the question of the causes of murmurs, but the results of their observations were practically all embraced in Corrigan's comprehensive work. Adams, in 1827, anticipated a good deal of subsequent work as regards the effects of mitral

obstruction on the chambers of the heart, and Hayden and others during the third quarter of the last century did almost all the work of importance on the subject of cardiac murmurs. Even so far back as 1772, M'Bride's "Practice of Physic" showed that slowness of the pulse in fatty disease was then known. Bellingham undoubtedly conceived the modern treatment of aneurism by dietetic and physical means. In his (the speaker's) own experiments he had proved to his satisfaction, and the satisfaction of others, the accuracy of conclusions which had been arrived at by Hunter, Adams and Stokes; and his observations had led him to expect that some time or other they should be able to hear a murmur of regurgitation at the pulmonary orifice like what was found in regard to the tricuspid orifice. The murmur had since been heard. In 1835 the Dublin Committee of the British Association stated that the auricles could produce sound on contraction. The observation was allowed to escape notice, and the subject did not emerge until about 1879 or 1880, when a distinguished graduate of Trinity College and he had studied a case of cleft sternum, and were always able to hear the movement of the auricles. Stokes had heard the same sounds. Other observers had taken up the subject, and it had occurred simultaneously to Professor Finny, the President of the Royal Academy of Medicine in Ireland, and to Professor Ritchie, his own clinical tutor, that the X-rays might be of use in the study of heart conditions. With the aid of lantern slides Dr. Gibson exhibited a series of tracings from his own studies in heart block. The slides showed the features during life and the pathological condition after death, and might, he held, be taken as proof positive that heart block was proved by the auricular sounds heard in the intervals between the apex pulsations.

The thanks of the Academy were conveyed to Dr. Gibson by the chairman, who was followed by Prossor Finny, Professor Little, Sir John Moore, and Professor W. H. Thompson.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

THE Winter Clinical Meeting of this society was held on December 19th, when a number of interesting cases was brought forward by members. Among the principal exhibits were pathological specimens by Prof. Annandale, Dr. Bruce, and Messrs. Cotterill and Cathcart.

Dr. GIBSON gave a demonstration of the use of Erlanger's sphygmanometer.

Dr. BYROM BRAMWELL showed cases of thrombosis of the pons and loss of the stereognostic sense from head injury.

Dr. BRUCE, cases of hæmorrhage into the optic thalamus, anterior poliomyelitis, primary myopathy, and disseminated sclerosis.

Dr. PHILIP, cases of chylous ascitis, extreme dyspnœa treated with Béraneck's serum, tuberculous glands healed with tuberculin.

Dr. EDWIN BRAMWELL, case of multiple syphilitic lesions of the nervous system and congenital paralysis of the face and ocular muscles.

A number of interesting surgical cases were also exhibited, among which a man, æt. 45, after incision and drainage of a mesenteric cyst containing brownish semi-fluid material, and a patient after incision, packing, and drainage of an enormous bleeding cavity in the right hypochondrium, believed to be due to an acute hæmorrhagic pancreatitis, shown by Mr. Alexis Thomson; a patient after removal of the Gasserian ganglion, by Mr. Cathcart; and cases of talipes equino-varus, treated by Lorenz's method, and of surgical tuberculosis treated by Tuberculin R. by Mr. Peel Ritchie, may be mentioned.

AN outbreak of scarlet fever is reported to have occurred at St. Andrew's. The original case has been traced to a dairy outside the burgh boundaries.

CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS ABROAD.

GERMANY.

Berlin, Dec. 23rd, 1906.

At the Society for Innere Medizin Hr. A. Fraenkel showed

PREPARATIONS OF INFANTILE PARALYSIS

and described the pathological anatomy.

Hr. Kraus asked if lumbar puncture had been performed, to which Hr. Fraenkel replied that it had for purposes of relief. From the clinical aspects of the case an infective disease might be assumed, as spinal paralysis sometimes occurred in epidemics.

Hr. Heubner had observed and performed an autopsy on a similar case of infantile paralysis twelve years ago. In regard to pathology it was remarkable how quickly the ganglionic cells were destroyed. This was in evidence in the preparations shown. Not long ago he performed lumbar puncture in a case, but did not find the meningococcus in the cerebrospinal fluid. He had also recently seen a case of cerebrospinal meningitis; possibly there was a connection between the two.

At the Hufeland Society Hr. Korte gave an address on

THE OPERATIVE TREATMENT OF GASTRIC ULCER.

It was uncertain how frequently hæmorrhage took place in gastric ulcer. Serbe placed the frequency at 1 per cent., Gerhardt and the English at from 13 to 18 per cent. In Berlin Brentano in 120,000 patients had 75 perforations amongst them, 46 women and 29 men.

The prognosis of perforation under internal treatment was bad; fatal peritonitis generally followed, recovery rarely. It was to be observed that in nervous persons a pseudo-perforation took place. The statement that 1 to 5 per cent. of recoveries took place was arbitrary. He had never seen a case. The prognosis was more favourable when perforation took place into adhesion and a subphrenic abscess formed. Mitsuliez was the first to operate in such cases. His first patient died. The first successful case in Germany was Heusler's. As regards recovered cases, England had at first the preponderance; in Germany the results were steadily improving. His own operation cases formed two series from 1890 to 1900 with 10 cases. Of these only one recovered, and even in this it was doubtful whether the perforation did not take place into adhesions. The second series gave better results. In these (19) the perforation was discovered and closed in 17; in two cases this was not done, as the diagnosis was incorrect. Of the 17 cases, 13 recovered and 4 died. The better results were due to earlier operation and not to improved technique; early operation was the most important of all the factors.

Twelve patients had stated that they had been treated before for stomach troubles. Two had had hæmorrage; 3 had had "weight" on the stomach; 4 declared that they had never suffered from any stomach affection. In four gastro-enterostomy had already been performed for abscess; in two cases the perforation took place at the juncture between the stomach and the intestine. Only two patients attributed the perforation to injury. Fulness of the stomach could not be the exciting factor of perforation. It happened in the morning after breakfast, which was not a copious meal. The patients collapsed at work; two after mid-day; but it might occur also in the night. The symptoms, especially at the commencement, were typical, so that diagnosis was easy. There was violent pain from irritation of the serosa of the peritoneum by the acid gastric juice. The most important sign was tension of the abdominal muscles. For the first few hours the abdominal walls were not distended, but board-like with tension, especially in the region of the rupture. After describing the well-

known symptoms, the speaker said that errors might be made. It was very unfortunate if the symptoms were attributed to the appendix, and this was cut down upon. The acid smell of the abdomen when opened showed the way to the correct spot. He had lost two cases from this error. The patients operated on within nine hours all recovered; all those operated on after 22 hours died.

The initial collapse was not a contra-indication of operation. In the early stages patients were given camphor, caffeine and saline infusions. In this stage an injection of morphia was useful. As regarded operation, the trinity of rules was: speedy operation, rapid finding of the perforation, cleansing of the abdomen and closure. A long incision was required.

The majority of ulcers were on the anterior wall, mostly near the pylorus; next on the lesser curvature and near the cardia. The opening was generally found on raising the left lobe of the liver. The opening was closed by simple suture; in many cases the edges had to be pared. A little bunch of omentum was stretched over the sutured parts. If the ulcer was near the pylorus, or if this was contracted, it was generally better to do a gastro-enterostomy. This was done in nine cases, two of which died.

A bacteriological cleansing of the abdominal cavity was impossible. It was best to wash out with physiological solution. The intestine might prolapse, and have to be punctured and emptied. The last remains of fluid would be absorbed.

In the after treatment analytics were given freely. Collapse generally took place in 10 to 12 hours. Patients were warmly wrapped up after operation, were given subcutaneous injection of camphor, caffeine and saline injections. A tablespoonful of tea every hour, etc. From the second week broths, etc., and meat from the third week. If the healing of the ulcer had not progressed the stomach was washed out with a weak solution of nitrate of silver, 1 : 2,000.

With rupture into adhesion patients did not die so readily. After a stormy commencement the symptoms quietened down; then a complex febrile condition supervened that lasted a long time, after which a subphrenic abscess formed. Of 12 patients with subphrenic abscess starting from the stomach, only six recovered.

AUSTRIA.

Vienna, Dec. 23rd, 1906.

Peripheral Facial Paralysis.

At the Gesellschaft für Innere Medizin Golreich exhibited a child, five months old, with left-sided facial paralysis, the result of malformation of the left ear. Congenital facial paralysis of this nature was a rare occurrence, and worthy of the society's consideration. The cause in this case was evident from the want of development in the bony structure of the ear, thus injuring the peripheral nerve in its course outwards.

Schüller related a similar case with this combination of otic malformation of the left ear and congenital paresis of the left facial nerve. He used electric stimuli to the nerve at once, and to-day the paresis is quite gone. There was no doubt as to the peripheral nature of the disease and the cause of the affection, which we must accept as mechanical.

Neurath gave a short history of an allied case of multiple malformations with neurotic symptoms, but which he diagnosed from the pathology as congenital "Kernaplasia."

Frey said that all otiatric literature recognised the connection of this form of paralysis in conjunction with this malformation of the parietal bones, middle and outer ear. The first defect was in the parietal bones, the second stage was the inhibition of the development of the facial, and the third change lay in the asymmetry of the skeleton of the face.

Swoboda differed from Frey in accepting paralysis as a constant factor in malformations of the ear and parietal bones, as he had seen cases with all these defects and no paralysis or paresis present. On the other hand, he had seen perfectly well-formed children with congenital facial paralysis. He could not believe that the atrophy of the facial region was a cause, but rather thought it was a result.

Aortic Aneurysm.

Weinberger demonstrated by means of the Röntgen rays a case of Aortic Aneurysm situated on the upper portion of the curve. It was firmly pressed against the left recurrent nerve, trachea and upper portion of the bronchus, causing atelectasis of the lower portion of the left lung. The heart and contents of the mediastinum were pressed far to the left of the thorax.

Desquamation of Nails.

Schick showed a twelve-year lad with the scarlet fever line well marked on all his finger-nails. These lines were observed about fourth week of the disease as crescentic lines passing forward to be shed like the epithelium of the skin, which he considered analogous.

FROM OUR SPECIAL CORRESPONDENTS AT HOME.

SCOTLAND.

Medical Officer for Edinburgh School Board.—The Edinburgh School Board has at length taken a step in the right direction in deciding to appoint a medical officer. It is impossible, however, not to sympathise to some extent with Councillor Lashman's objection to the report recommending this step, for the first regulation (and there are fifteen others) reads as follows: "He shall advise the Board as to new sites, plans of new schools, and also, when required, as to school apparatus; he shall exercise a general supervision over the ventilation, heating, lighting, and cleanliness of the schools; he shall periodically inspect all school lavatories and other sanitary installations, and he shall report immediately to the head-master, and, if necessary, to the superintendent of works, any insanitary conditions discovered." Councillor Lashman said that if they got a man able to do all implied in that regulation they were going to get a wonderful man, and went on to say that if they expected so much they should pay a salary of £4,000 rather than the £400 offered. It is to be supposed, however, that what is really demanded is that the new official shall guide the School Board in sanitary and other matters with an expert medical opinion; his duties should be critical rather than constructive, except in his own particular line, and probably the burden looks greater in the regulation than it would be in reality. With regard to the salary, we unhesitatingly say it is inadequate, as the medical officer appointed is required to give up his whole time to the work. This was apparently felt to some extent, for in his concluding remarks the Chairman of the Board said that, though they believed they could get a very good man for £400, it would be for the Board to give the matter further consideration if the attraction was not sufficient to secure the kind of man they wanted.

LETTERS TO THE EDITOR.

"OBJECTION TO DOCTORS."

To the Editor of The Medical Press and Circular.

Sir,—Together with the usual number of your admirable journal of to-day, December 12th, there is laid upon my table the *Times* and the mid-weekly issue of the leading local county paper. In your journal I notice an editorial paragraph with the heading of this letter, pointing out that patients will often bear for years excruciating suffering rather than see a doctor. There exists widespread distrust and dislike of the profession. Every practitioner must be aware of this; but perhaps everyone does not trouble to examine into

the causes. These causes are sufficiently well indicated in my two lay papers. In the *Times* appears a report of an anti-vaccination meeting. Mr. Lupton, M.P., enlarges upon the theme that vaccination is a "piece of eighteenth century quackery, a dangerous and useless practice." Lieut.-General Phelps discourses on the "Legends and fairy tales told by small-pox hospital authorities. The patients in those institutions die, not from small-pox, but from the treatment." Then there are the anti-vivisectionists, with three or four societies amply provided with funds. These fanatics hold up the most respected, distinguished, and self-sacrificing of medical scientists as fiends in human shape, delighting in the infliction of horrible torments upon animals, in spite of the demonstrated futility of their labours; and they suggest that the practices and teachings of these scientific men destroy the humane feelings of medical students—practitioners in process of manufacture. I send a sample from the county paper before me. This advertisement, enormous in size, and with huge capital head-lines, must cost some pounds weekly. It is only one of many of the same class appearing in all country papers. The vast outlay in advertisements is a measure of the extent to which the public is plundered. The advertisement teaches that the profession is of the types which the fanatics above named describe. It proclaims that disease is very simple, but it is the doctors that usually kill people; that the quacks can cure all maladies—the advertisement names scores of organic diseases—including consumption, paralysis, epilepsy, and Bright's disease; whilst cancer and rupture are cured without the operations which surgeons advise, with the result that the fools who submit to them are often ruined for life. The profession looks on at all this with perfect apathy, and the simple public are now the helpless victims of the most extensive of all the cruel systems of fraud that are at the present day carried on by the parasites of modern society.

I am, Sir, yours faithfully,

Reigate, Surrey, December 12th, 1906. S.

THE MOUTH AS A FOCUS OF INFECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am much obliged to "Hospital Dentist" for the kindly manner in which he refers to my paper. The space at my disposal was limited, or I should certainly have dwelt at greater length on the treatment of Pyorrhœa alveolaris, a subject which has long interested me in its bacteriological aspects. I should be the last to ignore the value of the services of our dental colleagues, to whom we owe so much. May I in return for the courtesy of "Hospital Dentist," venture to call his attention to an excellent lecture recently published on "Present Views on Diseases of the Joints," by Professor Howard Marsh, who refers to the frequency with which joint affections follow septic conditions of the mouth. He points out that the part played by the tonsils and the lymphatic tissues of the pharynx in harbouring agents by which the joints may be infected has only recently been fully appreciated, and gives details of two cases in which after carious teeth were cut down level with the gum and a new crown was applied, the patients became subject to what was regarded as acute osteo-arthritis involving several of the large joints, and those also of the hands. In both these, after operation by a dental surgeon, the joint affection was arrested.' I regret that I have not yet had an opportunity of seeing Mr. Sewill's "Manual of Dental Surgery," referred to, which is evidently regarded as authoritative.

I am, sir, yours truly,

FREDERICK NORMAN, F.R.C.S.

THE SYSTEMATIC LECTURE NUISANCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am pleased to see that someone (Sir Thomas Myles) has at last had the courage to attack that belated institution, the systematic lecture. As a student I always felt that attendance at these archaic functions was an egregious waste of time. I can conscientiously affirm that I learned very little from such lectures; the lecturer discoursed either of things I knew, in which case it was a labour of supererogation, or he wandered into realms not yet explored by me, in which case I was soon "off my feet," and failed to derive any benefit.

Abroad—in France at any rate—attendance at lectures is not compulsory, although it is thought good policy to make a point of occupying a foremost place for a few days before the examinations, in order that one's features might not be altogether strange to the lecturer, *qua* examiner.

We do not *read* medical books; we con them over and over again until the facts have acquired a footing in the memory. How many times such facts have to be recapitulated every student knows. What good, then, can it be to pass highly technical subjects rapidly in review before the bewildered minds of raw students.

The resistance to the abolition of the lecture system will come from "vested interests," and we may be sure that it will die hard. It had a *raison d'être* when books were scarce and costly, and when scientific writers had not yet learned how to classify and enforce their facts. One need only turn back to the text books of some thirty years ago to appreciate what I mean by that. Now, however, all is changed, and systematic "teaching" is an anachronism. No, theoretical, or rather systematic, learning is best obtained from books, especially now that they are so graphically illustrated, and the rest must be acquired in the laboratory and at the bedside. After all, it is only a question of time, though I do not look to the General Medical Council to assist any movement in this direction.

I am, Sir, yours faithfully,

ICONOCLAST.

STAGHUNTING AND VIVISECTION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read your comments on a recent Surrey Staghunt, and there is no getting away from the sting of them. Though I abominate the practice of vivisection, I cannot see how I could logically denounce it, if I did not strongly reprobate the cruelties carried on by sportsmen.

The very name "*sportsman*" is condemnatory. How can a person ever be justified in torturing or killing creatures for simple amusement? The thing is absolutely immoral; and if sporting people would only reflect a little they would surely see it in this light. If a butcher boy told us he found delight in the slaughter of cattle, we should warn him against developing into a criminal. Such being the case, why should it be deemed laudable conduct when the upper classes mow down hand-reared pheasants, leaving many wounded to crawl away and die a lingering death, or turn out park deer and chase them time after time to the point of exhaustion, or hunt to death foxes, otters, hares, and the wild stags of Exmoor? These creatures could all be killed with less pain than they are by the means employed.

How can we call this country a Christian land when such sports go on? Why is not the pulpit made an instrument for reforming these sporting cruelties out of existence? It is a scandalous thing that some of the clergy are their patrons. The democracy must take the matter in hand and generate more worthy ideas.

I am, sir, yours truly,

Wokingham, Dec. 21st. (REV.) J. STRATTON.

VEGETARIANISM AND ALCOHOL.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In one of his recent works Maeterlinck advances as a argument in favour of a vegetarian diet that a taste for alcohol is created by indulgence in meat, and that when this is abandoned the alcohol habit follows suit. I was struck by the remark, and have since taken advantage of my opportunities to see whether there was any ground for the assertion. I began by trying the experiment of a vegetable meal, and I certainly felt disinclined to take either wine or beer with it. Inasmuch, however, as I hanker

after the fleshpots, I transferred my attention to sundry patients who appeared to have much to gain by the adoption of a non-meat dietary. I imposed no restriction in regard to alcohol in any form, leaving them free to follow their inclinations. Without a single exception I found that so long as they persevered with the regimen I had laid down they ceased to derive any satisfaction from strong drinks; indeed, two of them deliberately returned to their ordinary food because, forsooth, they said they "could no longer either drink or smoke with any degree of satisfaction." I do not remember any chronic inebriates among my acquaintances, professional or social, and the only one I ventured to approach on the subject declined to have anything to do with my suggestion.

I feel convinced that there is a co-relationship between meat-eating and alcohol drinking, and if this be so it is a point worth bearing in mind in the organisation of the homes for inebriates now in course of construction.

I am, sir, yours truly,

ALFRED S. GUBB, M.D.

Mustapha Superieur, Algiers.
Dec., 1906.

OBITUARY.

ALFRED SHEEN, M.D., D.P.H., M.R.C.S.

By the death of Dr. Alfred Sheen on December 16th, Cardiff lost one of its most respected medical men. Dr. Alfred Sheen had a varied career. Born in Leicester, he was educated at Hurstpierpoint, and in 1855 went to Madras to take up a Civil Service appointment. The work, however, was not congenial, and Mr. Sheen entered the Madras Medical College, where he was a student until 1860, taking a number of prizes. Returning to England, he completed his medical studies at Guy's Hospital, and qualified in 1862 as M.D. (St. Andrews) and M.R.C.S. (Eng.). He came to Cardiff in 1864 as house surgeon at the infirmary, and held that appointment until 1866, when he went into practice. Dr. Sheen was appointed hon. surgeon to the Cardiff Infirmary in 1871, and resigned that position after twenty years' service. In 1900 he was appointed consulting surgeon. Dr. Sheen was also visiting medical officer at the Cardiff Workhouse for thirty-six years, and wrote a book entitled, "The Workhouse and Its Medical Officer," which was accepted by Poor-Law Medical officers as a standard work. Dr. Alfred Sheen was one of the founders of district nursing in Cardiff, and was president and hon. treasurer of the Jubilee Nurses' Institute, and also acted as hon. medical officer. He was a member of the council of the University College of South Wales and Monmouthshire for many years, and took great interest in the medical school, giving a scholarship which is awarded annually.

WALTER J. SYKES, M.D., D.P.H., F.I.C.

We regret to record the death of Dr. Walter John Sykes, of East Grinstead, who passed away in his sleep on December 16th. Dr. Sykes was an M.D. (Edin.) a member of the Council of the Public Analysts' Society and editor of the *Analyst*, and late Medical Officer of Health and Public Analyst for Portsmouth Borough. He was also the author of "Principles and Practice of Brewing." He took a great interest in music, and was conductor of the East Grinstead Orchestral Society. He was 64 years of age, and had resided at East Grinstead for nearly ten years.

JOSEPH HARRISON, L.R.C.P., L.R.C.S.Edin., L.S.A.

The death of Dr. Joseph Harrison, which took place on December 18th, in his sixty-fourth year, removes from Bradford a well-known personality. Dr. Harrison who lived practically all his life in Bradford, was originally an operative in the wool trade. He worked with great diligence at the Bradford Mechanics' Institute, where he carried off a number of diplomas in the Society of Arts examinations. Afterwards he became a teacher of science, and his services were in considerable request in many parts of the West Riding. Becoming a student at the Leeds School of Medicine, he was admitted a licentiate of the Royal College of Physicians of Edinburgh in 1879, and a licentiate of the Royal College of Surgeons of Edinburgh in 1883, taking also a medal in practical chemistry. Since then he followed the medical profession.

MEDICAL NEWS.

Metropolitan Asylums Board.

At an ordinary meeting of the managers of the Metropolitan Asylum District, held at the office of the Board, on the Embankment, on Saturday week, Mr. A. C. Scovell presiding, Mr. Ecroyd moved:—"That the General Purposes Committee be instructed to consider and report as to the advisability of discontinuing the river ambulance service and arranging for the transport of future small-pox patients by road." He said the river ambulance steamboats used for the conveyance of small-pox patients were obsolete and practically useless, while their upkeep cost £7,000 a year. Mr. J. T. Helby seconded the motion on the ground that an inquiry might be advantageous. Sir Robert Hensley said the reference was absolutely futile and premature. During the small-pox epidemic of 1901-2 the number of patients conveyed to small-pox institutions daily varied between 50 and 100, and this mode of conveyance was, in his opinion, preferable to conveyance by motor-cars, as had been suggested. Professor Smith said the river ambulance service was of a most admirable kind. It represented years of development and of thought, and any one of the ambulance steamers to-day was about as perfect as any of the hospital wards which the Board had under its control. He thought that nothing would justify an alteration of the system. After further discussion the motion was adopted. The returns of infectious cases showed that during the fortnight ended last Thursday week 1,159 patients had been admitted to the Board's fever hospitals, 64 had died in those institutions, and 1,268 had been discharged recovered; the total number remaining under treatment being 5,270, as compared with 5,443 a fortnight previously. Of that number, 4,051 were sufferers from scarlet fever, 1,051 from diphtheria, and 168 from enteric fever. There were no small-pox patients under treatment.

A Bogus Doctor.

On December 4th, George Gill, aged 50, was charged at Burnley with falsely pretending to be a surgeon. Evidence was given that in March last the accused carried on practice as a doctor in Abel Street. He had on his window "Dr. G. Gill, Provident Medical Dispenser." A Mrs. Butterworth consulted him about her child. The following month he again attended the child, and said it was suffering from the same complaint as before. He gave it some medicine. The child died in a day or two, and accused being unable to give a certificate an inquest was held. Gill was summoned to this, but decamped, and was only apprehended a week ago. Gill said he had been in the army and had had some amount of medical training. He was fined £10 and costs or two months.

Royal College of Surgeons of Edinburgh.—The Fellowship.

The following gentlemen, having passed the requisite examinations, were at a meeting of the College held on 17th inst., admitted ordinary Fellows:—W. C. Allardice, M.D., J. Brydon, L.R.C.S.Eng., C. V. Cornish, M.R.C.S.Eng., H. S. Davidson, M.B., Ch.B., D. Dickie, M.B., Ch.B.; H. Norman Goode, M.B., M.R.C.S.Eng., H. W. Illius, M.R.C.S.Eng., R. W. Johnstone, M.D., T. W. Kirby, M.D., M.R.C.S.Eng., J. R. Lee, M.B., T. E. Lloyd, M.R.C.S.Eng., J. P. Morton, M.B., L.R.C.P.Eng., T. Y. Simpson, M.D., M.R.C.S.Eng., H. Stuart, M.D., M.R.C.S.Eng., and F. W. Sydenham, M.D.

WEEKLY SUMMARY OF THE MEDICAL JOURNALS, ENGLISH AND FOREIGN.

Specially compiled for THE MEDICAL PRESS AND CIRCULAR.

RECENT PATHOLOGICAL LITERATURE.

Carcinoma in Mice.—Clowes (*British Medical Journal*, December 1, 1906) publishes a comprehensive account of the investigations into cancer in mice, conducted in the New York State Laboratory. (1) He finds that the primary tumour is only transplanted with difficulty. After the first generation the yield of tumours gradually increases until a maximum virulence is obtained, which subsequently remains fairly constant. Thus in the case of one tumour the first transplantation only gave positive results in 5 mice out of 28 (17 per cent.), with a long average period (over 74 days) between inoculation and the fatal result, whereas at the fifteenth generation 91 per cent. of the inoculations gave results, with a period of 25 days. In the case of a less virulent tumour, inoculation failed altogether in the early generations, unless the material were incubated at a temperature between 38.5 degrees C. and 41 degrees for half an hour before injection. At the seventh generation, 57 per cent. of inoculations with the incubated material were positive, and 20 per cent. with the normal. The material for inoculation was in all cases obtained by grinding up a tumour with salt solution in a mortar, and removing the shreds of connective tissue. (2) Increase of virulence is associated with increased rate of growth. This has been shown by the parallelism observed between positive results of inoculation and shortening of the period before death. (3) Incubation of material before inoculation increases its virulence until a maximum has been reached. (4) The resistance of tumour cells to disinfectants is high. It was found possible to destroy the bacteria in badly infected tumours without seriously affecting their virulence. (5) Tumours with a high potassium and micro-proteid content are more virulent than those with a low potassium and high calcium content. (6) Immunity to cancer occurs in mice. Mice which have recovered spontaneously from cancer cannot be affected by tumours of an equal degree of virulence, and they exhibit a high resistance to tumours of greater virulence. Moreover, the serum from mice which have recovered exerts a definite action when injected into tumours in other mice. Inoculation, however, with tumour material treated by a high temperature or by chemicals in such a way as to render development impossible, entirely fails to confer immunity. Inoculation with micro-proteid extracts of tumours is also without effect. Clowes also discusses with reference to Ehrlich the possibility of tumour formation being due to the stimulus given to certain cells by the presence of a toxin, and he inclines to the view that such is the case, and that the toxin is the result of the activity of a parasite which has infected the cell. R.

Examination of the Blood.—Gulland (*Scottish Medical and Surgical Journal*, December, 1906) discusses the methods of clinical examination of the blood available for general practitioners, and illustrates their value by reference to points of practical diagnosis. The paper does not profess to contain anything new, but it is both comprehensive and terse. (1) Estimation of hæmoglobin can be conveniently made by the Tallqoist hook, or, if more accurate results are required, by Haldane's instrument. Gulland illustrates the need for a hæmoglobin estimation in cases of supposed chlorosis by recounting the history of a patient with normal amount of hæmoglobin, who, by reason of poor circulation, and thick skin, looked pale, and was treated unsuccessfully by hæmatinics for months. Again, the determination of the colour index is of great importance in distinguishing the various forms of anæmia. (2) Enumeration of the red corpuscles is best done by Thoma's instrument. (3) For counting the leucocytes Thoma's apparatus is also recommended, using as diluting fluid a 1 per cent. watery solution of acetic acid, coloured light green by methyl green. (4) Films are most easily stained by Jenner's stain, which Gulland thinks superior to any of its modifications. He is right in emphasising the fact that almost the whole art of making films lies in proper cleansing of the cover-glass. "If the cover-glasses are clean, almost anyone can make good films. If they are not clean, no one can do so. (5) The presence of glycogen granules in polymorphonuclear leucocytes is detected by dropping the film on a drop of dilute iodine (1 in 100) solution. Gulland regards a positive reaction as of great importance, signifying the presence of a toxæmia. The more marked the reaction, the more severe the toxæmia. It is commonly due to infection by the pneumococcus, the streptococcus, the staphylococcus, or the bacillus coli, but may be due to other infections, or to such conditions as uræmia and morphia poisoning. Gulland illustrates the advantages of careful blood examinations by showing their bearing on the diagnosis of such diseases as phthisis, pneumonia, typhoid, appendicitis, and puerperal sepsis. R.

Gastric Erosions.—Miller (*British Medical Journal*, December 1, 1906) publishes an account of a hitherto undescribed condition said to account for the occasional hæmorrhages into the stomachs of dyspeptic patients. One of the changes occurring in gastritis is inflammation of the lymphoid follicles. They disintegrate and soften, and eventually burst, leaving a bare spot of the basement membrane. This undergoes gastric digestion, and the underlying vessels, having first formed small aneurisms, are likewise eroded, hæmorrhage resulting. The less healthy the mucous membrane, the more likely is the erosion to become extensive, since in the case of a healthy tissue repair is rapid. Miller accompanies his paper by illustrative photographs, showing various stages of the process he describes. R.

The Action of Röntgen Rays on Spermatozoa.—Attention has frequently been drawn of late years to the action of the X-rays on the reproductive organs, and particularly on spermatozoa. Bardeen (*British Medical Journal*, December 15th, 1906) publishes a brief note regarding the effect of X-rays on the spermatozoa of toads. He finds (1) that their fertilising power is lessened by exposure to the rays; (2) ova fertilised by such spermatozoa may die early or may develop into tadpoles, which, however, always show some abnormality; (3) the nervous and vascular systems are chiefly affected, but all the organs are more or less abnormal; (4) the abnormality may show a tendency to be unilateral. R.

The Evidence for Opsonins.—The doctrine of opsonins has up to the present rested almost entirely on the evidence adduced by English and American experimenters. On the Continent, both in France and Germany, Wright's views have so far failed to gain general support. Thus, Löhlein, of Leipsig, issues from Metchnikoff's laboratory, and presumably with his assent, a depreciatory criticism of the teachings of Wright, Douglas, Hektoen, Bulloch, and others, on the subject of phagocytosis *in vitro* (*Annales de l'Institut Pasteur*, November 25th, 1906). He has made experiments with the anthrax bacillus, the streptococcus, the bacillus coli, and the cholera vibrio, and he comes to the following conclusions:—(1) Phagocytosis *in vitro* only depends in a restricted number of cases on the presence of favouring substances (opsonins) in the free state. If it be true that phagocytic

action only takes place with the help of these bodies, then it must be admitted that they may be provided by the leucocytes themselves. (2) The normal serum of guinea-pigs contains bodies which by their action on certain pathogenic organisms prepare them, in certain cases especially, for phagocytosis. (3) These bodies are active at a temperature of 0 degree C., but are destroyed by a temperature of 55 degrees C. They have a constitution resembling that of agglutinins in that they consist of two groups. They are to be distinguished from bacteriolysins, from bacteriolytic sensibilisatrices, and from complements, but it is not at present possible to distinguish them from the agglutinins of normal serum. (4) The introduction of the term "opsonins" is unjustified, for these bodies play the part ascribed by Metchnikoff to "fixateurs."

R.

Spirochætes in the Lung.—Castellani and others have reported the discovery of spirochætes in the hæmorrhage of hæmoptysis, no other organism being discovered to account for any lesion. Branch (*British Medical Journal*, December 1, 1906) reports a case of phthisis with hæmoptysis in which spirochætes in large numbers were observed. Two distinct types were seen: (1) a stout, strongly stained organism, with regular curves, probably the *spirochæte refringens;* (2) a more delicate form, with closer waves, nearly resembling the *s. pallida*, but staining easily with ordinary aniline stains. The sputum was remarkably tenacious, and Branca has observed that ulcers, where *s. refringens* was present, showed a peculiarly viscid secretion; he suggests that the presence of the spirochæte may have to do with this viscidity in both instances. Although not regarding either of the forms observed as *s. pallida*, he notes that the patient had signs of old syphilis.

R.

The Histological Structure of Koplik's Spots.—Hlava (Casopis Pekaru Ceskych, 1906, p. 773) has excised the spots from the inside of the cheek in five cases of measles, and has examined them histologically. There existed in the neighbourhood of each a local hyperæmia and leucocytal infiltration, and in addition there was extensive keratinisation of the epithelium, with excessive desquamation. In the centre of each spot the basal epithelium was necrosed and liquefied, and in some cases there was an underlying small collection of pus, which was closely confined by the hardening of the surface cells. The keratinisation of the mouth epithelium is on a par with the changes that occur in the skin in measles, the only exception being that the process extends further from its centre, and is more often associated with vesico-pustular formation. Koplik's spots are, in short, the exanthem of measles occurring in the mucous membrane of the mouth, and becoming pustular. M.

Phlegmonous Inflammation of the Stomach and Œsophagus.—A case of this very rare condition is recorded (*Deutsch. Archiv. für Klin. Med.*, Bd. 87, H. 5 and 6). The patient, æt. 21, without apparent cause, began suddenly to suffer from severe pain in the neck and from dysphagia. The pain gradually extended down into the chest, swallowing became impossible, the larynx and pharynx were found to be enormously swollen, and death took place in seven days from general collapse. The necropsy showed an extensive purulent inflammation of the whole œsophageal and gastric wall, chiefly localised in the submucous coat. The superficial epithelium was intact, but purulent extensions were found here and there throughout the mediastinal tissue. The cause remained unrevealed, but it was suspected that the inflammation originated in the throat, perhaps as a result of some slight injury by a foreign body. From there it rapidly spread, producing the inflammation as described. M.

Pseudo-Chylous Ascites.—Zyptein reports two cases of this condition (*Weiner Klin. Woch.*, 1906, No. 34). After a study of the literature and as a result of his own investigations, he concludes that as yet no definite opinion can be expressed as to the nature of the substance which produces the characteristic appearance of these effusions. He conjectures that it is caused by certain chemical substances which are not present in ordinary serous effusions, and which have not yet been isolated; but it is possible to imagine that the qualitative chemical grouping of pseudo-chylous effusions is identical with that of simple ones, and that the only real change consists in the presence of an unusual quantity of some one ingredient, for example, lecithin, nucleo-albumin, or mucin. In the cases described by the present writer it was noticed that the intensity of the milky opalescence always decreased when the quantity of albumin present increased. M.

Digestion of Fat in the Stomach.—That a certain amount of fat is split up in the stomach has now been definitely established, but it is still a matter of doubt as to whether the splitting up is due to a ferment actually secreted in the stomach, or to a regurgitation of pancreatic juice from the duodenum. Heinsheimer has endeavoured (*Arbeit. aus dem path. institut zu Berlin*) to solve this problem by experiments on dogs. He has obtained gastric juice direct from the stomach by means of a gastric fistula, and also from isolated stomach pouches. Both products broke up fat to a slight extent, the digestion being most complete when the reaction was acid. From this it is concluded that the stomach itself must secrete a lipolytic ferment, as no communication with the intestine existed in the cases where a stomach pouch was made. It was, moreover, noted that the pancreatic ferment can only act in a neutral or alkaline medium. The gastric ferment was very scanty, and disappeared altogether after a few days. It is present also to a slight extent in human gastric juice, and as obtained from it will act in a neutral, acid, or faintly alkaline medium. M.

Phlegmonous Gastritis.—To the eighty cases of this condition that have been reported in the literature, Schnarwylen now adds and describes three. In the condition one distinguishes a circumscribed form or abscess, and a diffuse infiltration or phlegmonous inflammation in a true sense. The submucous coat is the principal site of the pathological changes. The stomach wall itself may be six times its normal thickness, and on the cut surface small purulent areas may be seen. Occasionally the abscess points into the stomach cavity, but much more frequently it extends peripherally, and affects the peritoneum. Etiologically one must distinguish between a primary and a secondary variety. In the first variety streptococci present in the food infect small traumatic lesions of the mucous membrane; while in the second variety pyæmic abscesses form in the course of puerperal or other general infections. Gastric ulcer and gastric carcinoma do not in any way predispose to the disease. The clinical symptoms are not typical, but have a close resemblance to those of peritonitis. The prognosis is bad, most cases terminating fatally within from one to twenty days. The only possible treatment is laparotomy and drainage, if a diagnosis is made. M.

Professor E. H. Starling, M.D., F.R.S., gave evidence before the Royal Commission on Vivisection on Wednesday and Thursday last.

Friday last, December 21st, was the sixtieth anniversary of the first operation performed under anæsthetics in Great Britain. The operation was performed at University College Hospital by Robert Liston, F.R.S. ether being the anæsthetic used.

Dr. Gustave Schorstein, whose death was announced on November 24th, has, states the *Lancet*, bequeathed £500 to the Regius Professor of Medicine at the University of Oxford for the Pathological Department of the Medical School, £500 to the London Hospital, and a sum which will probably amount to some £10,000 in trust to the University of Oxford, subject to certain life interests. When these are expired the capital is to be at the disposal of the University for use as that body shall think fit.

NOTICES TO CORRESPONDENTS, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate, providing authors give notice to the Publisher or Printer before the type has been distributed. This should be done when returning proofs.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance.

SERMO.—Poikilocytosis occasionally is very slightly marked in pernicious anæmia, so that the doubtful appearance of the blood in the case mentioned cannot be held to exclude the condition. It is a valuable point in the diagnosis if the majority of the red corpuscles are larger than normal, especially if there are some very large ones. Microcytes are not now regarded as pathognomonic, as they are found in other diseases. The leucocytes are practically always fewer than normal, and sometimes, especially towards the termination of a case they reach a very low figure.

THE COST OF A STOMACH-ACHE.

A GOOD definition of appendicitis was given by a recent sufferer. He said that it was a modern pain that cost about £200 more than the old-fashioned stomach-ache.

INSURED.—Touts of the kind are far too common, and their impudence is appalling. It is far better to have nothing to do with them. There are recognised and unrecognised ways of doing business, and though an agent's forwardness and impertinence does not necessarily condemn the office as unsound, they certainly fail to cast credit on it. Write to their headquarters.

DR. N. S.—It is possible that your case may be one of tubercle of the lacrymal gland, but very unlikely. The condition has been recorded, but always in connection with tuberculosis elsewhere. Excision of the gland is the proper treatment.

L. D. S.—Yes, foot and mouth disease is communicable to man. It is supposed to be contracted from infected milk or directly from diseased animals. If due to an organism, as is highly probable, it must be able to pass through a porcelain filter, as the filtrate is still capable of reproducing the disease.

R. N. L.—The pancreas may be the seat of congenital syphilis. The arteries show periarteritis and the adventitia is infiltrated with lymphoid cells. It is curious that the islands of Langerhaus do not seem to be primarily involved.

A TOUCHING INCIDENT.

ONE of those dramatic incidents which in a novel would appear incredible, happened at South Kensington Station a night or two ago. You have doubtless heard of the doctor who was killed in trying to board a moving train. This writer has heard the rest of the story from the doctor at St. George's Hospital who received the hopeless "case." When he was picked up on the platform, the officials at once sent for the doctor who was usually summoned to railway accidents at South Kensington. "The doctor has just left home," was the answer. "You must send some one at once," was the call, and the woman at the other end of the telephone, who was a doctor's wife and had been a nurse, said that she would come and do her best. She came to the station, lifted the head of the dying man, and saw the face of her own husband. They say that doctors are callous. But the doctor who saw the tense-faced woman whose husband had been summoned to cure himself, and herself had filled the place, had a tremor of emotion in his voice.—*Daily Chronicle.*

MR. WILTON (Liverpool):—The mortality unfortunately remains about the same, notwithstanding the discovery referred to.

INDIAN MEDICAL SERVICE.

THE next examination of candidates for Commissions in the Indian Medical Service will be held in London on Tuesday, January 29, 1907, and the four following days. Particulars regarding pay, promotion, &c., in the Service, and the necessary forms of application can be obtained from the Military Secretary, India Office, London, S.W. Immediate applications, duly filled up and accompanied by the required certificates, must be made at once. The number of vacancies is eighteen.

DR. S. (Manchester).—We understand the book is now out of print, and as its author has recently died there is no probability of another edition.

DR. L. H.—Such a movement as you suggest has already been set on foot in America. In July this year a committee of the Suffolk (U.S.A.) District Medical Society was appointed as a Milk Commission. The objects were, at the outset, simply to encourage the production of clean milk and to certify milk submitted to them. Excellent regulations were drawn up by them, and the services of the members of the commission were purely honorary

NURSE A. R. G.—Yes, we believe that hospital nurses will count as "workmen" under the new Compensation Act. Although not specifically mentioned, and not domestic servants in the usual sense of the word, we are advised that nurses will come under the provisions of the Act. But it does not come into force till July next, so that the case you cite will have no redress except at common law.

M. A. B.—No organism has yet been assigned a causative rôle in typhus on any undubitable grounds. The best authenticated one is *micrococcus exanthematicus*, described by Lewaschef, and also by Dubief and Brühl. But the whole subject is very obscure.

R. S. O. (Somerset).—We shall be glad if you can communicate with us in London. The article you send is very interesting and we hope to be able to use it if space permits. But we should like to have your address.

Vacancies.

Edinburgh School Board.—Medical Officer. Salary £400 per annum. Applications to G. W. Alexander, Clerk, School Board Offices, Edinburgh.

County Borough of Salford.—Fever Hospital.—Assistant Medical Officer at the Ladywell Sanatorium, Salford. Salary £150 per annum, with apartments and board. Applications to L. C. Evans, Town Clerk, Town Hall, Salford.

King Edward VII. Sanatorium, Midhurst, Sussex.—Pathologist. Salary £250 per annum, with board, lodging, and attendance. Applications to the Hon. Secretary, 19 Devonshire Street, Portland Place, W.

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary £150 per annum, all found. Applications to the Medical Superintendent.

Newport Borough Asylum, Caerleon, Mon.—Assistant Medical Officer. Salary £150 per annum, with board, apartments, and attendance. Applications to the Medical Superintendent.

Royal Mineral Water Hospital, Bath.—Resident Medical Officer. Salary £100 per annum, with lodging, board, and laundry. Applications to the Secretary.

South Devon and East Cornwall Hospital, Plymouth.—House Surgeon. Salary £100 per annum, with board, residence, and washing. Applications to P. J. Langdon, Secretary.

Great Northern Central Hospital, Holloway Road, N.—Casualty Officer. Salary £100 per annum. Applications to L. H. Glenton-Kerr, Secretary.

Parish of Paddington.—First Assistant to the Medical Superintendent of the Infirmary and Assistant Medical Officer of the Workhouse. Salary £120 per annum, together with board, lodging, and washing. Applications to the Medical Superintendent at the Infirmary, 285 Harrow Road, W.

Down District Asylum, Downpatrick. — Junior Assistant Medical Officer. Salary £130, rising to £150, per annum, with board, &c. Applications to M. J. Nolan, Resident Medical Superintendent. (See advt.)

Appointments.

CUNNINGHAM, RICHARD G., M.B., Ch.B.Edin., House Physician and Pathologist at Sunderland Infirmary.

CURRIE, JAMES, M.B., M.S.Edin., Certifying Surgeon under the Factory and Workshop Act for the Springhead District of the county of York.

ECKENSTEIN, K. E., M.R.C.S., L.R.C.P., Clinical Assistant to the Chelsea Hospital for Women.

FINLAY, DOUGLAS EDWARD, L.R.C.P.Lond., M.R.C.S., Public Vaccinator to the City of Gloucester.

HOPEWOOD-SMITH, L.R.C.P.Lond., M.R.C.S., L.D.S.Eng., the External Examiner in Dental Subjects for the Third and Final Examinations for the Degrees in Dental Surgery of the University of Birmingham.

HUTCHINSON, J. R., M.B., Ch.B.Vict., D.P.H.Vict., Assistant Medical Officer of Health of the County Borough of Blackburn.

TROTTER, WILFRED B. L., M.D.Lond., F.R.C.S.Eng., Assistant Surgeon to University College Hospital.

WILLCOX, W. H., M.D.Lond., Physician to the Great Northern Central Hospital, Holloway Road, N.

Birth.

GARDINER.—On Dec. 16th, at 1 Queen's Avenue, Muswell Hill, the wife of Douglas Gardiner, M.B., C.M., of a son.

Marriage.

WILKINSON—GOVETT.—On Dec. 19th, at St. Paul's Church, Fisherton, Salisbury, Alfred Hugh Wilkinson, fifth son of the late F. Wilkinson, of Cleveland House, Barnes, to Catherine Elizabeth Govett, youngest daughter of the late Philip William Govett, Staff Surgeon R.N., of Plymouth, and of Mrs. Govett, of Salisbury.

Deaths.

BIRD.—On Dec. 19th, at 1 Trafalgar Square, Fulham Road, Kate widow of Dr. Arthur Hinckes Bird.

CLARK.—On Dec. 15th, at 9 Park Circus, Ayr, Scotland, Elizabeth Mayston, widow of John Andrew Clark, Surgeon, late Bengal Army.

EASTLAKE.—On Dec. 17th, Margaret, wife of the late Henry E. Eastlake, M.D., of Welbeck Street, Cavendish Square, London.

3 GAL 104
